- b. **Severe combined immunodeficiency (SCID)** is a phenotypic term for a wide range of congenital and inherited immunologic defects that include the loss of both B- and T-cell systems. Most patients experience severe, recurrent infections that begin in the first few months of life. Some of the genetic defects result in defective T-cell signaling through cytokine receptor mutations or kinases involved in cytokine signaling (JAK3 kinase). Still other defects are in genes important for TCR complex signaling (CD3) or genes encoding recombinase enzymes required for gene rearrangement in TCR and BCR generation. Mutations in genes that control class II MHC expression result in a condition known as bare lymphocyte syndrome, which functionally presents as SCID, because class II MHC expression is necessary for T<sub>H</sub> cell development in the thymus. Most SCID patients will not survive the first year of life unless the immune system is reconstituted by hematopoietic stem cell transplantation.
- B. **Secondary immunodeficiencies.** Defects in immunity that are secondary to another cause are more common than primary causes.
1. **Malnutrition** is the most common cause of immunodeficiency disorders worldwide, and malnourished individuals often experience an increased incidence of infectious diseases, an impaired response to vaccination, defects in cell-mediated immunity, and defective phagocyte function, all of which reverse following adequate nutritional support.
  2. Patients with **lymphoproliferative diseases**, such as leukemia and myeloma, are also prone to infection. These patients experience varying degrees of hypogammaglobulinemia and impaired antibody responses; some lymphoproliferative diseases also lead to defective cell-mediated immune function.
  3. In developed countries, immunodeficiency is often due to specific **medical treatment**. Therapeutic agents such as x-rays, cytotoxic drugs, and corticosteroids can have dramatic effects on the immune system. Immunosuppressive drugs, such as used to prevent organ transplant rejection or used to suppress autoimmune reactions, can also affect lymphocyte and neutrophil activity.
  4. Some **microorganisms** suppress the immune response, particularly cytomegalovirus, measles, rubella, Epstein-Barr virus, and some bacterial infections, such as tuberculosis, leprosy, and syphilis.
  5. **AIDS** is a late stage of a progressive infection with **HIV**. HIV (either HIV-1 or HIV-2, although HIV-1 is more common in the United States) selectively infects CD4-bearing cells leading to a gradual depletion of T<sub>H</sub> cells. AIDS is defined by the presence of certain opportunistic infections and cancers including *Pneumocystis* pneumonia; disseminated cryptococcosis; histoplasmosis; toxoplasmosis; mycobacterial disease; persistent, ulcerative herpes simplex virus infection; Kaposi sarcoma; and disseminated cytomegalovirus infection. There are many specific targets for antiretroviral therapy, including reverse transcriptase inhibitors, protease inhibitors, integrase inhibitors, and fusion inhibitors (reviewed more specifically in Chapter 36, “Infectious Diseases”). Early intervention using a combination of drugs, while monitoring CD4+ cell count and viral load, allows for tailored treatment regimens to achieve the best results for individual patients (i.e., highly active antiretroviral therapy or HAART). There are no known cures and no effective vaccines available for HIV, although there are clinical vaccine trials ongoing.

## VI. HYPERSENSITIVITIES

- A. **Overview.** Under some circumstances, immune responses produce damaging and sometimes fatal results, known collectively as *hypersensitivities*. Hypersensitivity reactions differ from protective immune responses in that they are exaggerated or inappropriate and damaging to the host. Hypersensitivity reactions are classified by the immune mechanism (*Figure 57-4*).
- B. **Type I hypersensitivity** reaction (also known as immediate hypersensitivity) occurs upon the reaction of allergen (an antigen that elicits an allergic response) with specific IgE antibody that is bound to high affinity receptors on the surface of mast cells and basophils.
1. **Sensitization phase.** Initial contact with the allergen leads to proliferation and differentiation of the specific T<sub>H</sub> and B-cell populations. This is known as sensitization and does not generate allergic symptoms. After sensitization, IgE associates with mast cells and allergic reactions can be elicited upon reexposure to the allergen. All normal individuals can make IgE specific for a variety of different antigens; however, some individuals (atopic) are more prone to developing IgE and experiencing allergic responses. The tendency to develop IgE-mediated responses does appear to have a genetic component. The pattern of inheritance is not yet understood, although MHC-linked genes appear to be involved in some cases.

**Figure 57-4.** The four main types of hypersensitivity reactions. **A. Type I** hypersensitivity is mediated by allergen-specific IgE antibody bound to the mast cell by virtue of the IgE Fc receptors. When allergen binds to the IgE, the mast cell is activated to release the inflammatory mediators contained within the mast cell granules. **B. Type II** hypersensitivities are mediated by the presence of a foreign antigen adsorbed to a host cell or tissue, in this case a red blood cell. IgG binds to the associated allergen, and immune reactants (i.e., complement) mediate damage to the host cell. **C. Type III** hypersensitivities are due to the accumulation of antigen–antibody complexes that lodge in the body and mediate damage within the tissue and vasculature via complement and phagocytic cells (neutrophil). **D. Type IV** hypersensitivity reactions are mediated by T cells ( $T_H1$ ,  $T_H2$ , or CTL), which also often activate macrophages through the production of cytokines. RBC, red blood cell.

- 2. Activation phase.** Cross-linking and clustering of the mast cell-bound IgE by the presence of allergen leads to the rapid release of mast cell granules containing many preformed inflammatory mediators (histamine, proteases, and  $TNF-\alpha$ ) and the synthesis of longer acting agents (leukotrienes, prostaglandins, and cytokines) that mediate the late phase response. The initial degranulation occurs within minutes, whereas the late phase response usually begins within 4 to 6 hrs and can last 24 hrs. Direct activation of mast cells via non-IgE-mediated events can also lead to the clinical features resulting from rapid mast cell degranulation. Complement components (C3a and C5a) act directly on mast cells, as do some food additives and certain drugs (e.g., aspirin, angiotensin-converting-enzyme [ACE] inhibitors, opioids) in some sensitive patients.

3. **Effector phase.** The symptoms of the type I hypersensitivity reactions are due to the inflammatory mediators released by the activated mast cells.
  - a. **Histamine** binds rapidly to a variety of cells via histamine receptors;  $H_1$  and  $H_2$  receptors are chiefly involved in the type I hypersensitivity reaction. Histamine binds to  **$H_1$  receptors** on smooth muscles (airway constriction, gastric muscular contractions) and endothelial cells (vascular permeability). Binding of histamine to  **$H_2$  receptors**, chiefly present at mucosal surfaces, results in increased mucous secretion and increased gastric acid production.
  - b. **Cytokines and chemotactic factors** are important for the growth and differentiation of leukocyte cell types, such as  $T_H2$ s and eosinophils, as well as recruitment of leukocytes, including eosinophils and neutrophils.
  - c. **Leukotrienes** and **prostaglandins**, which are both synthesized as part of the late phase response, lead to prolonged constriction of smooth muscle (bronchoconstriction) and continued vascular permeability.
4. **Clinical presentations of type I hypersensitivities**
  - a. **Allergic rhinitis** is the most common atopic disorder worldwide. Airborne allergens react with IgE-sensitized mast cells in the nasal mucosa and conjunctiva, resulting in degranulation of these mast cells, increased mucous secretion, localized vasodilation, and increased vascular permeability. Typical respiratory allergens include grass, tree, and weed pollens; fungal spores; dust mite allergens; and pet dander.
  - b. **Asthma** is a syndrome characterized by a generalized but reversible **airway obstruction, bronchial hyperresponsiveness, and airway inflammation**. Asthma cannot be explained solely based on IgE-mediated mast cell processes; however, most cases occur in patients who also show immediate hypersensitivity to defined environmental allergens. Airway inflammation plays a major role in the pathogenesis of asthma; recruitment of inflammatory cells, particularly eosinophils, can ultimately lead to remodeling of the respiratory tissue (further described in Chapter 41, “Asthma and Chronic Obstructive Pulmonary Disease”).
  - c. **Food allergies** are caused by the intake of certain foods that then interact with sensitized mast cells of the GI tract. Mast cell degranulation and mediator release leads to smooth muscle contraction (nausea and vomiting) and increased mucous and acid secretion. Typical food allergens include nuts, eggs, milk, and shellfish. In some cases, the food can be absorbed systemically, leading to mast cell degranulation in the skin (hives or atopic urticaria) or anaphylaxis from systemic mast cell degranulation.
  - d. **Anaphylaxis** is due to a generalized degranulation of IgE-sensitized mast cells following allergen exposure and is characterized by bronchospasm and cardiovascular collapse. Common allergens associated with anaphylaxis include bee and wasp stings, certain foods, and drugs (most notably, penicillin).
5. **Clinical tests for allergies and intervention.** Sensitivity is normally assessed by the introduction of small amounts of allergen into the skin either via **skin prick (scratch test) or intradermal injection**, followed by assessment for the wheal and flare (swelling and redness) reaction within 30 mins. Alternatively, allergen-specific **serum IgE** can be measured by radioallergosorbent test (RAST) or the enzyme-linked immunosorbent assay (ELISA). Skin tests and antigen-specific IgE blood tests are not always an accurate assessment for food allergies.
6. **Treatments**
  - a. For some patients, the easiest means to control allergies or asthma is to **avoid exposure** to known allergens or asthma triggers.
  - b. Modulation of the immunologic response or **desensitization** by injection of small amounts of allergen can lessen the hypersensitivity reaction to those specific allergens. Desensitization is thought to occur via a stimulation of  $T_H1$  cells rather than  $T_H2$  cells and, in some cases, a production of increased amounts of IgG rather than IgE. Recent desensitization clinical trials using oral introduction of allergen shows promise, particularly with respect to food allergies, and is thought to occur via the stimulation of  $T_{REG}$  cells. Sublingual immunotherapy (SLIT, currently used in Europe for desensitization to environmental allergies) and specific oral tolerance induction (SOTI, used in investigational studies) are not currently approved by the U.S. Food and Drug Administration (FDA) and are considered experimental.

- c. Another strategy in the treatment of severe, persistent, allergic asthma uses an **anti-IgE monoclonal antibody** (omalizumab) to inhibit the binding of IgE to the mast cell.
  - d. **Mast cell stabilization.** Cromolyn sodium (sodium cromoglycate) renders mast cells more resistant to triggering and activation.
  - e. **Mediator antagonists.** Antihistamines (ethanolamines, most notably diphenhydramine) are H<sub>1</sub>-receptor competitive antagonists of histamine. Cimetidine and ranitidine competitively inhibit histamine H<sub>2</sub> receptors. Specific treatments for asthma are discussed in Chapter 41, "Asthma and Chronic Obstructive Pulmonary Disease." Epinephrine acts through its  $\alpha$ -agonist and  $\beta$ -agonist effects and is the most important drug for the treatment of anaphylaxis.
- C. **Type II hypersensitivities** are antibody mediated and are due to the production of IgM or IgG antibodies directed to foreign antigens associated with cell surfaces. The targeted cell is either damaged or destroyed by complement activation, either direct lysis or opsonization; antibody-dependent, cell-mediated cytotoxicity via NK cells or eosinophils; or opsonization by antibody, followed by phagocytosis by neutrophils and macrophages. Certain drugs, as well as blood group antigens (e.g., ABO incompatible transfusion reactions or Rh hemolytic disease), may act as type II hypersensitivity antigens (ABO transfusion reactions will be further discussed in section IX.B).
1. **Type II drug reactions.** Drugs acting as haptens may become associated with cells or other components of the body and initiate antibody formation. When associated with the surface of red blood cells, drugs (e.g., penicillins, cephalosporins, and quinidine) can result in hemolytic anemia. Other drugs (e.g., quinine) more often attach to platelets and produce thrombocytopenia. The sensitization phase of a type II hypersensitivity reaction to a drug requires approximately 7 to 10 days after the initiation of drug therapy, at which point, antibody production will be sufficient for cell lysis and inflammation. Subsequent exposure to the drug will result in symptoms more rapidly (approximately 3 days or less). Withdrawing the drug typically resolves the symptoms.
  2. The **Rhesus blood group** (Rh antigen) is a protein antigen, most often the D polypeptide; anti-Rh antibodies are the leading cause of **hemolytic disease of the newborn** (HDN). During pregnancy of an Rh-negative mother with an Rh-positive child, the mother may become sensitized to the D antigen of the child's blood. Sensitization usually occurs at or near delivery and does not affect the source child. However, subsequent Rh-positive children may develop HDN when maternal IgG, including anti-D antigen antibodies, are passed across the placenta into the neonate during the third trimester. Rh-negative women are administered RhoD immune globulin (RhoGAM) during the latter part of pregnancy and within 72 hrs of delivery of an Rh-positive child in an effort to prevent sensitization. The passive immunization with the anti-RhoD antibodies acts by binding fetal blood cells that may be in the maternal circulation.
- D. **Type III hypersensitivity** reactions are mediated by **immune complexes** of foreign antigen together with IgG, or occasionally IgM antibodies. The presence of the immune complexes results in activation of complement, including the generation of chemotactic and vasoactive factors. The classic immune complex allergic disorders include the Arthus reaction, serum sickness, and hypersensitivity pneumonitis (farmer's lung).
1. **Arthus reactions** are localized cutaneous inflammatory reactions due to the immune complexes and inflammation that form in dermal blood vessels following the **localized injection** of large amounts of antigen into a sensitized individual. Antigen sources for Arthus reactions include drug injections (e.g.,  $\beta$ -lactam-based antibiotics, heparin, incidental foreign proteins in injectable products such as fetal calf serum), vaccines, insect stings, and spider bites. Arthus reactions are characterized by an **edematous and erythematous reaction**, occurring within 3 to 8 hrs at the site of the antigen injection. The reaction will resolve without intervention, although hemorrhagic ulceration at the site is not uncommon. A limited form of Arthus reaction occurs commonly at the site of allergy desensitization and usually subsides in less than 24 hrs.
  2. **Serum sickness** is a systemic immune complex reaction that occurs after injection of large quantities of foreign material. The antigen-antibody complexes deposit in small blood vessels, where complement-generated inflammation gives rise to the clinical features: **fever, joint pain, urticaria, and splenomegaly**. Typical antigens for serum sickness include heterologous antiserum (e.g., antivenin for snake, scorpion, and spider bites), antitoxins, intravenous human gamma globulin, and intravenous drugs. After initial injection, symptoms of primary serum sickness begin to appear as the antibody response develops (usually 7 to 10 days). In patients already sensitized to

the antigen, symptoms appear more quickly (usually 2 to 4 days after injection). Complications of serum sickness are rare, and the symptoms usually resolve as the antibody response increases and the immune complexes are more efficiently removed from the body. Treatment is largely symptomatic.

3. **Inhalation of antigenic particles** or fumes can result in a hypersensitivity pneumonitis due to antigen-antibody complexes and the subsequent inflammation that forms in the lungs. Inhalation of environmental fungal spores or other organic particles, especially *Aspergillus* spores in **farmer's lung**, appears to generate both **IgE and IgG** to the inhaled antigens as well as **T<sub>H</sub>1 cells**. The combination of the IgE- and IgG-mediated reactions, together with the action of proinflammatory cytokines, leads to tissue damage, inflammation, and the typical symptoms, which could be described as **asthma symptoms superimposed with fever, cough, and sometimes chronic lung damage**. Avoidance of antigen exposure is an important feature of management; repeated episodes lead to bronchial wall weakening and pulmonary fibrosis. High-dose systemic corticosteroid therapy is necessary to resolve the acute allergic inflammation and prevent long-term lung damage.
- E. **Type IV hypersensitivities (delayed-type hypersensitivities)** are mediated by specific effector **T cells**. Examples of type IV hypersensitivities include the immune response to some infections (tuberculosis) and contact dermatitis, most often associated with metals or haptenic chemicals.
1. One of the best known examples of a type IV hypersensitivity is the **tuberculin skin test** (Mantoux skin test). Injection of purified protein derivative (PPD) into the skin of an individual previously infected with *Mycobacterium tuberculosis* recruits and activates those cells currently or previously employed in response to the tubercule bacillus (i.e., T cells and macrophages). A positive tuberculin skin test will present with **redness and a palpable induration at 48 to 72 hrs** after administration.
  2. Many chemical substances, natural and synthetic, can be the source of **contact hypersensitivity**, which is typically a type IV hypersensitivity reaction. Common allergens include metals (nickel and chromate), plastics, rubber, lanolin, latex, plant chemicals, and medications such as neomycin and phenothiazines. The plant oil urushiol is the immunogenic hapten that is responsible for the contact dermatitis associated with **poison ivy**. The reaction is characterized by a red rash within a few days of contact, bumps, patches of weeping blisters on the skin, swelling of the area, and intense itching. Effective treatment focuses on suppressing the T-cell response: topical steroids such as triamcinolone or clobetasol. If the affected area involves more than 20% of the body or is particularly severe, systemic corticosteroid therapy may be required. Inhalation of the allergen when the plants are burned can lead to severe allergic respiratory issues.
  3. **Celiac disease**, also known as **gluten-sensitive enteropathy**, is considered an autoimmune disorder that is triggered by a cell-mediated, adaptive immune response to ingested gluten, such as that found in wheat gluten and related proteins in rye and barley. In genetically susceptible individuals (i.e., HLA-DQ2 or -DQ8), gliadin, gluten's main antigen, associates with host proteins. Development of the symptoms of the disease is associated with **T<sub>H</sub> and T<sub>C</sub> lymphocytic** infiltration in the gut epithelial membrane and lamina propria, expression of proinflammatory cytokines, and production of IgA and IgG antibodies directed against the gluten as well as host components (e.g., tissue transglutaminase). **Inflammation, villous atrophy, and crypt hyperplasia** in the small intestine are all characteristic of celiac disease. Extraintestinal symptoms can include bone and skin disease, anemia, endocrine disorders, and neurological deficits. Gluten-free diet is the only effective intervention for celiac disease.

**VII. AUTOIMMUNITY** is an immune response that is directed against self-antigen(s); autoimmune diseases are conditions where the autoimmune response is responsible for the tissue or organ damage.

- A. **Mechanisms of breakdown in tolerance.** Autoimmunity requires a breakdown in the mechanism of self-tolerance. During the development of the lymphocyte repertoire in the bone marrow and thymus, T and B cells with self-reactive receptors are eliminated or rendered anergic (unresponsive) to prevent immune system self-reactivity. Additional mechanisms of peripheral tolerance are also involved in controlling self-reactive lymphocytes.
1. **Genetic factors.** Autoimmune diseases tend to run in families. The genetic contribution to autoimmune diseases often involves multiple genes; however, there are some genetic components

that are associated with increased risk for the development of certain autoimmune disorders. Many of the strongest and best characterized **genetic associations with autoimmune disorders** involve different variants of MHC/HLA: HLA-B27 and increased risk of ankylosing spondylitis, HLA-DR3 or -DR4 and increased risk of insulin-dependent diabetes mellitus (IDDM), HLA-DR4 or -DR1 and increased risk of rheumatoid arthritis, and HLA-DR2 and a protective effect for the development of IDDM.

2. **Hormonal influences.** There is a general trend for autoimmune disease to occur more frequently in women than in men, probably due to differences in hormone profiles. The precise mechanism is unknown.
  3. **Infection. Molecular mimicry**, or shared/similar epitopes in pathogen antigens and self-antigens, can elicit autoimmune disorders (e.g., immune reactivity to group A streptococcal M proteins and the development of rheumatic fever). Additionally, infection in a target organ induces the expression of co-stimulatory molecules and the presentation of pathogen and self-antigens through the action of IFN- $\gamma$ .
- B. Organ-specific autoimmune disorders** usually affect a single organ, most often an endocrine gland.
1. **Hashimoto thyroiditis** involves the infiltration of mononuclear cells, including lymphocytes, macrophages, and plasma cells, into the thyroid, resulting in destruction of follicular cells and a general breakdown in the architecture of the thyroid. The immune mechanisms involve antibody and cell-mediated components. The resulting **hypothyroidism** is treated with synthetic thyroid hormone replacement (levothyroxine sodium also known as Synthroid, Levoxyl, Levotheroid, or Unithroid).
  2. **Graves disease** is the result of antibodies that act as agonists of thyroid-stimulating hormone (TSH) by binding to the TSH receptor and stimulating the release of thyroid hormones. The resulting **hyperthyroidism** is treated by antithyroid drugs (e.g., propylthiouracil or methimazole) or thyroid ablation by radiation or surgical removal, which would then be treated with synthetic thyroid hormone replacement therapy.
  3. **Rheumatic fever** is due to the production of antibodies directed against the M proteins of group A streptococci (GAS), which are cross-reactive to antigens present in the heart. Early identification and antimicrobial treatment during an infection with GAS is important to prevent the formation of the antibodies. Repeated streptococcal infections can lead to further damage to the heart tissue (rheumatic heart disease).
  4. **Autoimmune-hemolytic anemia** (erythrocyte), **-thrombocytopenia** (platelet), **-neutropenia** (neutrophil), and **-lymphopenia** (lymphocyte) are mediated by antibodies directed against antigens intrinsic to the cell surface of the affected blood cell. It is important to discriminate between type II hypersensitivity-mediated cellular destruction, which is often due to the transient presence of extrinsic antigens on the surface of the cell, and autoimmune disease, which would be due to immune activity toward self-antigens. Autoimmune responses may need immunosuppressant therapy to halt the destruction, whereas hypersensitivity is often self-limiting and resolves when the extrinsic antigen is no longer present. For autoimmune hemolytic anemia, transfusions may be required. **Plasmaphoresis** to remove self-reactive antibodies or splenectomy can slow the erythrocyte destruction in severe cases.
  5. With **myasthenia gravis**, antibodies are directed against the **acetylcholine receptor** (ACh-R) on the motor end plates of the muscle cells, blocking the binding of acetylcholine and mediating complement-dependent damage to the receptor and cell membrane. The patient experiences variable **skeletal muscle weakness**, often appearing first as drooping eyelids, double vision due to an impairment of extraocular eye muscles. Acetylcholinesterase inhibitors, neostigmine (Prostigmin), pyridostigmine (Mestinon and Regonol), and others are the first line of treatment, followed by corticosteroids for long-term control, or other immunosuppressants (e.g., cyclosporine or azathioprine) for more severe cases.
  6. **Insulin-dependent diabetes mellitus** (IDDM or type I diabetes) is caused by the selective destruction of the islets of Langerhans of the pancreas. Destruction involves T cells and often antibodies directed against antigens in the pancreatic  $\beta$ -cell, the primary producer of insulin. Disease symptoms appear when the destruction is nearly complete and the insulin levels are low. Increased risk of developing IDDM is associated with HLA-DR3 and -DR4. Current therapy targets the replacement of the insulin (see Chapter 46, "Diabetes Mellitus"). Immunotherapeutic approaches to consistently and safely prevent or reverse IDDM have not been developed in humans.

7. **Goodpasture syndrome** is characterized by **progressive glomerulonephritis** and frequently, pulmonary hemorrhage (particularly in those who smoke). The tissue damage is due to the production of antibodies directed against antigens of type IV collagen, which is present in the basement membrane in the lungs and glomeruli. The risk of developing Goodpasture's is strongly associated with certain variants of HLA-DRB1. Patients are treated by plasmapheresis, followed by systemic corticosteroids, and often cyclophosphamide.
  8. **Multiple sclerosis (MS)** is an inflammatory, demyelinating **neurodegenerative**, autoimmune disease of the central nervous system. The exact immune mechanism is not completely understood; however,  $T_H1$  cells and the inflammatory cytokines that they secrete (e.g.,  $IFN-\gamma$ ) are strongly implicated. The clinical features, which include sensory disturbance and motor dysfunction, can be highly variable and dependent on many factors, such as the sites of pathological lesions and the rate of new lesion formation. Treatment strategies focus on reducing the inflammation within the CNS, and include interferon  $\beta$ -1b (Betaseron and Extavia), interferon  $\beta$ -1a (Avonex and Rebif), glatiramer acetate, mitoxantrone, fingolimod, and natalizumab.
- C. **Non-organ specific or systemic autoimmune diseases** affect multiple organs, usually associated with antigens found throughout the body.
1. **Sjögren syndrome (SjS)** is a complex, chronic autoimmune disease, which is characterized by mononuclear cell infiltration of **exocrine glands** resulting in reduced or loss of secretory function. SjS may present as either primary SjS or as secondary, occurring in association with other autoimmune diseases, such as rheumatoid arthritis, systemic lupus erythematosus, or other connective tissue disorders. The precise immune mechanism is not completely understood. Mild cases are treated with artificial tears, medications for dry eyes (cyclosporine ophthalmic emulsion and hydroxypropyl cellulose ophthalmic inserts), medications for dry mouth (cevimeline, and pilocarpine hydrochloride), and frequent drinking of water. Systemic manifestations often require immunosuppressive therapy, such as systemic corticosteroids, to treat internal organ manifestations or severe flares.
  2. **Rheumatoid arthritis (RA)** is a chronic, recurrent, systemic inflammatory disease that principally involves the joints. It is characterized by the presence of rheumatoid factors (autoantibodies directed against the Fc portion of IgG) in the serum and synovium, infiltration of lymphocytes and activated macrophages into involved joint synovium, and local production of  $TNF-\alpha$  and other proinflammatory cytokines in involved synovium. Therapy is generally aimed at reducing synovial inflammation in order to improve symptoms and preserve joint function. Specific therapeutic interventions are discussed further in Chapter 42, "Osteoarthritis and Rheumatoid Arthritis."
  3. **Systemic lupus erythematosus (SLE)** is a systemic autoimmune disorder directed to self-antigens that are present in all or nearly all cells of the body, most typically nuclear components, such as nucleic acids and nucleoprotein particles. The immune complex formation initiates inflammatory reactions leading to cell and tissue destruction. **Symptoms are variable depending on the site of immune complex formation** and may be intermittent, which complicates diagnosis. Joint pain and swelling are the most common symptoms. Other symptoms include fatigue, fever with no other cause, malaise, hair loss, mouth sores, skin rashes (described as a butterfly rash on the face in some patients), sensitivity to sunlight, and swollen lymph nodes. For individual patients, the course of the disease is highly variable in terms of severity, the organs and tissues involved, and the progression of the disease. Mild disease may be treated with nonsteroidal anti-inflammatory drugs (NSAIDs) and corticosteroid creams for the skin rashes. Hydroxychloroquine (Plaquenil, an antimalarial medication) is sometimes useful in patients whose symptoms have not improved with other interventions. Belimumab (Benlysta), a monoclonal antibody inhibitor of B cells, is a newly FDA-approved drug for use in SLE. More severe cases of SLE are often treated with high-dose corticosteroids or cytotoxic drugs (e.g., cyclophosphamide). When flares have subsided, the dose can often be lessened to reduce side effects. Drug-induced lupus erythematosus is similar to SLE in terms of the clinical presentation; however, it is caused by a hypersensitivity reaction to a medication (e.g., chlorpromazine, hydralazine, isoniazid, methyldopa, penicillamine, procainamide, quinidine, and sulfasalazine). Symptoms tend to occur after taking the drugs for at least 3 to 6 months, and they tend to resolve when the medication is discontinued.

**VIII. TUMOR IMMUNOLOGY** involves the antigenic properties of the transformed cell, the host immune response to the tumor cells, the effect of the growth of the tumor may have on the body, and the potential manipulation of the immune response to eradicate the tumor.

- A. Overview. Cancer** results from a single cell that has undergone multiple mutations that lead to **uncontrolled cell growth**. Tumors can be **benign** (encapsulated, local, and limited in size), **malignant** (continually increasing in size and encroaching on adjacent tissues), or **metastatic** (spreading out from the primary tumor to form secondary tumors often at distant sites). Exposure to chemicals, radiation, viruses, or accumulated errors during replication can facilitate the malignant transformation.
- B. Immune recognition of cancers**
1. Malignant tumors express molecules that may be recognized by the immune response. Tumor-specific antigens are expressed on tumor cells, but not on normal cells (e.g., viral proteins). Tumor-associated antigens are expressed on tumor cells but can also be found on normal cells, although often in smaller amounts or on cells of a different developmental stage (e.g., p53 and CT antigens).
  2. **MHC class I chain-related (MIC) proteins** are stress-induced proteins that are often expressed on the surface of transformed epithelial cells, which can then be recognized by **NK cells** and **CTLs**. Tumor cells that express tumor antigens via class I MHC are recognized and killed by CTLs. Tumor cells that alter gene expression to reduce class I MHC presentation are recognized and killed by NK cells.
  3. Several types of cancers are associated with chronic viral infections. By preventing infection, vaccinations protect against cancers caused by those viruses (e.g., human papillomavirus vaccine and hepatitis B vaccine).
- C.** Monoclonal antibodies directed against tumor antigens can be used for diagnosis and therapy, either alone via typical antibody-mediated mechanisms or conjugated to cytotoxic drugs or radioactive isotopes. Examples include rituximab (Rituxan), trastuzumab (Herceptin), and ibritumomab (Zevalin, conjugated to <sup>111</sup>I). Additional specific chemotherapy agents are discussed in Chapter 50, “Cancer Chemotherapy.”

**IX. TRANSPLANTATION** is complicated by the antigenic differences between donor and recipient, the most important of which are antigenic differences in the HLA class I and class II molecules (also known as transplantation antigens).

- A. Autograft** is transplantation of tissue from one site to another on the same person, as might be used for the treatment of severe burns, and does not require immunosuppressive therapy. A **syngeneic transplant** (or isograft) is a transplant between genetically identical individuals and also does not require immunosuppressive treatment. **Allograft** (or allogeneic transplant) is a transplant between two genetically different individuals and often requires immunosuppressive therapy due to allo reactions (either graft rejection or graft versus host reaction, depending on the type of tissue transplanted). Specific immunosuppressant therapy is discussed further in Chapter 53, “Immunosuppressive Agents in Organ Transplantation.”
- B. Transfusion** is a form of “living transplant” whereby blood is removed from one person for infusion into another. Human erythrocytes lack HLA classes I and II molecules. Major antigenic determinants of erythrocytes include the ABO glycolipids and the Rhesus (Rh) erythrocyte antigens. In routine ABO blood grouping, if antigens are absent from a person’s erythrocytes (A or B carbohydrates), then antibodies, usually IgM, that recognize those antigens naturally develop due to structural similarities between the A and B carbohydrates and the carbohydrates present in gut bacteria. As such, persons of blood type O would make anti-A and anti-B antibodies, whereas blood type AB would make neither set of antibodies. If the recipient of a blood transfusion is making antibodies that recognize antigens found on the transfused blood, then the newly transfused erythrocytes will be lysed by complement and phagocytes. Patients experience fever and chills associated with the hemolysis of the transfused blood. The Rh blood antigen (most typically, the D antigen) is a protein antigen; Rh-positive individuals have the protein antigen, and Rh-negative individuals do not. The production of antibodies does not occur until the D antigen is introduced into the body and recognized as foreign by Rh-negative individuals (Rh immunization). Anti-Rh antibodies are the leading cause of HDN (discussed in section VI.C.2).

- C. **Transplantation of solid organs.** Common solid organ transplants are kidney, heart–lung (in combination or separately), pancreas, and liver (with or without intestine segment).
1. **Hyperacute rejection** is the result of preformed antibodies against ABO blood group antigens or HLA antigens. These preformed antibodies act with complement, which leads to immediate destruction of the tissue and occlusion of the graft blood vessels, usually within minutes or hours of transplantation. Once established, no treatment is available to reverse the effects. ABO incompatible kidney transplants have been successfully performed in investigational studies in Japan, Europe, and the United States by performing plasmapheresis of the recipient before and after transplantation.
  2. **Acute rejection** is caused by effector T cells that are responding to HLA differences between donor and recipient. Acute rejection takes days to develop and can be reduced or prevented by the use of immunosuppressant drugs prior to and after transplantation.
  3. **Chronic rejection** occurs months or years after transplantation and is characterized by a gradual thickening of the vasculature of the transplanted tissue. As the lumen of the vessel walls narrow, the blood supply to the grafted tissue is eventually reduced, causing ischemia and tissue death.
  4. Matching of donor and recipient HLA class I and class II allotypes improves the outcome of organ transplantation. The need for HLA matching and immunosuppressive therapy varies with the organ transplanted. The cornea of the eye can be transplanted without consideration of HLA type or immunosuppressive therapy because the cornea is not vascularized, and the immunological environment of the cornea suppresses inflammation. Liver cells express very low levels of HLA class I and class II antigens. Good HLA match between donor and recipient for liver transplantation can reduce the incidence of acute rejection; however, it does not appear to influence the overall graft outcome. Bone marrow transplantation is the most sensitive to HLA mismatches.
- D. **Hematopoietic stem cell transplantation** (bone marrow transplantation). Bone marrow transplantation is often used as a treatment for many genetic diseases that affect cells of the hematopoietic system, including many immunodeficiencies, and some cancer treatments, particularly those with immune system cancers. Hematopoietic stem cells are infused into the patient whose own bone marrow has been weakened or destroyed due to the immunodeficiency or cancer treatment. The grafted bone marrow cells repopulate the hematopoietic system of the recipient. Recipient rejection of the graft bone marrow is less of a concern because the recipient immune system is typically immunodeficient; however, the donor marrow is immunocompetent and can lead to **graft versus host disease** (GVHD). In GVHD, mature T cells ( $T_H$  or  $T_C$ ) that are present in the donor graft respond to the recipient HLA allotypes. The donor T-cell response can occur in any tissue, although the skin, intestines, and liver are principally involved. Almost all bone marrow transplant recipients experience some degree of GVHD, although the severity tends to correlate with the degree of HLA mismatch. In addition to reducing the incidence of GVHD, it is important that the donor and recipient match for at least one HLA class I and one HLA class II allotype in order to reconstitute the immune system.

## X. VACCINATION

- A. **Overview.** **Passive vaccination** is the introduction of antibody, either whole serum, concentrated immune (gamma) globulin that is mostly IgG, or purified IgG, to provide immediate protection. Passive immunization is useful for patients who cannot form antibodies (immunodeficient) or for the patients who might develop disease before active immunization could stimulate antibody production. Passive immunization is temporary, lasting several weeks to several months for each administration. **Active vaccination** is the intramuscular, subcutaneous, or oral introduction of antigen(s) to stimulate a specific immune response. Protection through memory varies with the vaccine, but immunity is long lasting.
- B. **Passive vaccination** (Table 57-2)
1. **Human immune globulin** is prepared from pooled plasma, usually from thousands of adult donors. The antibody preparation is mostly IgG and reflects the immunity of the donor pool. Although rare, contamination by viruses is possible. Three different preparations are available: **immune gamma globulin for intramuscular** use (IGIM), **immune gamma globulin for**

**intravenous** use (IVIG or IGIV), and **specific immune globulins** with a high content of antibody against a particular antigen (for intravenous or intramuscular use).

- a. Standard human serum immunoglobulin for intramuscular use (IGIM)** is a polyclonal immune globulin preparation from pooled plasma of donors and is typically used to prevent or reduce the severity of certain viral diseases, such as hepatitis A, measles, varicella, and rubella, or for IgG deficiency in adults and children. Adverse reactions include angioedema, pain, and inflammation at the site of the injection, urticaria, and, in rare instances, anaphylaxis. IGIM should never be administered intravenously due to the presence of high-molecular-weight immunoglobulin aggregates that can lead to serious systemic reactions.
- b. Immune globulins for intravenous use (IVIG)** are prepared from pooled human serum and modified to minimize antibody aggregation. There are many preparations of IVIG, which are supplied either as a lyophilized powder or sterile solution. The concentration, rate of administration, and dosing interval varies with the preparation and the underlying reason for treatment. The advantage of IVIG is the ability to administer large doses of immune globulin

**Table 57-2** SELECTED PASSIVE VACCINES<sup>a</sup>

Vaccine Name	Description (Source) <sup>b</sup>	Typical Use
Black widow spider antivenin	Antiserum (equine)	Prophylaxis, therapy
Botulinum antitoxin	Botulism antiserum (equine) to trivalent toxin	Prophylaxis, therapy
Cytomegalovirus immune globulin (CMV-IGIV) for intravenous use (CytoGAM)	Anti-CMV-enriched serum product (human)	Prophylaxis of CMV disease associated with transplantation of kidney, lung, liver, pancreas, and heart
Hepatitis B (HepB) immune globulin (HBIG), intramuscular use	Anti-HepB-enriched serum product (human)	Prophylaxis
Immune globulin for intramuscular use (IGIM)	Polyclonal, pooled immunoglobulin, mostly IgG (human)	Prophylaxis (hepatitis A <sup>c</sup> , measles, varicella, and rubella); therapy for IgG deficiency
Immune globulin, human, for intravenous use (IVIG)	Polyclonal, pooled immunoglobulin, mostly IgG (human)	Preferred therapy for IgG deficiency; therapy for idiopathic thrombocytopenic purpura; prophylaxis (hepatitis A <sup>c</sup> , measles, varicella, and rubella)
Rabies immune globulin (RIG) for intramuscular and/or subcutaneous use <sup>d</sup>	Anti-rabies enriched, pooled plasma (human)	Prophylaxis
Respiratory syncytial virus (RSV-MAb, palivizumab) for intramuscular route <sup>e</sup> (Synagis)	Anti-RSV monoclonal antibody (humanized)	Prophylaxis in high-risk populations
RhoD immune globulin (RhoGAM)	Anti-Rho(D)-enriched serum product (human)	Prophylaxis during pregnancy and after delivery of Rh+ by Rh- mother
Snake bite antivenin	Crotalidae polyvalent antiserum (equine)	Prophylaxis, therapy
Tetanus immune globulin (TIG) for intramuscular use	Anti-tetanus toxin enriched serum product (human)	Prophylaxis
Varicella zoster immune globulin for intramuscular use	Anti-varicella zoster enriched serum product (human)	Prophylaxis, therapy in immunocompromised patients

<sup>a</sup>Not all passive vaccines nor approved uses included.

<sup>b</sup>Valence indicates the number of antigenic types included in synthesis of the vaccine preparation.

<sup>c</sup>Hepatitis A active vaccination within 2 weeks of exposure is preferred over IGIM prophylaxis for those < 40 years of age; IGIM should be used for children aged < 12 months, adults > 40 years, immunocompromised persons, and persons with chronic liver disease.

<sup>d</sup>Administered into the depth of and around the bite wound if possible; remainder administered IM.

<sup>e</sup>RSV-MAb (monoclonal antibody) is preferred over human immune globulin (RSV-IGIV).

and a more rapid onset of action. IVIG is particularly valuable as replacement therapy for the **management of primary immunodeficiency disorders** and for the management of idiopathic thrombocytopenic purpura and Kawasaki disease. Side effects include fever, nausea, abdominal pain, and vasoactive phenomena (usually vasodilation), although slow administration reduces these side effects. Patients with IgA deficiency may develop severe anaphylactic reactions after IVIG infusion due to the trace amounts of IgA in the IVIG preparations.

- c. **Special preparations of human immune globulin** are serum products that contain high specific antibody content. Most are available in the intramuscular form; a few are for intravenous use.
  - d. **Animal antisera.** Equine (horse) antisera prepared from hyperimmunized horses are used in certain situations. Antibody derived from animals can produce an immune response in humans that leads to rapid clearance of protective antibodies and the risk of allergic reactions, particularly **serum sickness** or **anaphylaxis**. Animal serum should not be given without inquiring about prior exposure or allergy to animal products. When administering animal-derived antiserum, epinephrine should be available.
2. **Rationales for passive vaccination**
- a. **Prophylaxis of infectious disease.** Antibodies are given prophylactically to prevent or reduce clinical symptoms of a viral or bacterial infection, particularly in a patient without previous exposure and therefore without immunologic memory. The vaccine protects the recipient during the incubation period for infection. For example:
    - (1) **Tetanus immune globulin (TIG)** is used to prevent tetanus following injury in patients whose immunization is uncertain or incomplete.
    - (2) **Hepatitis B immunoglobulin (HBIG)** is administered to a newborn child of a woman with hepatitis B or to nonimmune individuals as soon as possible after exposure to hepatitis B.
  - b. **Prophylaxis or therapy** prevents or attenuates the effects of infection in special populations. Examples are **varicella zoster immunoglobulin (VZIG)** is given to patients with leukemia or immunocompromised patients who have been exposed to the varicella zoster virus; cytomegalovirus human immune globulin is used for the prophylaxis of CMV disease for recipients of kidney, lung, liver, pancreas, and heart transplants. IVIG or IGIM, pooled sera containing a broad spectrum of IgG specificity, is often administered following exposure to some viral illnesses (see *Table 57-2*).
  - c. **Treatment of antibody deficiency.** Individuals who are deficient in antibody production, either because of primary immunodeficiency (see V.A.3) or as a result of chronic lymphocytic leukemia, receive IVIG or IGIM every 2 to 4 weeks to maintain humoral immunity. IVIG is generally preferred.
  - d. **Other situations.** IVIG is used for idiopathic (autoimmune) thrombocytopenia purpura. Intramuscular RhoD immunoglobulin (RhoGAM) is used prophylactically for Rh disease (see section VI.C.2). Muromonab-CD3 (OT3) is a mouse-derived monoclonal antibody that binds to CD3 on the surface of T cells. T cells become opsonized with bound muromonab-CT3 and are targeted for destruction in the liver. Muromonab-CD3 is used in the treatment of acute renal graft rejection and in some circumstances, acute rejection of liver and heart transplants.
- C. **Active vaccination** is the administration of an antigen to elicit a protective immune response. (**Specific vaccines** in common use and recommended administration schedules are listed in *Table 57-3*.) The anamnestic response when reencountering antigen is both stronger and faster, and provides potential protection.
1. **Overview**
    - a. **Contents.** Active vaccines contain one or more subunits of a pathogen or whole pathogenic organisms but may also contain preservatives, low doses of antibiotics, and other compounds that do not affect the immune response.
    - b. **Administration.** Active vaccines are administered subcutaneously, intramuscularly, intradermally, orally, or intranasally. Some are introduced adsorbed to aluminum hydroxide or aluminum phosphate adjuvants. An **adjuvant** is a vaccine addition that increases the antigenicity of the vaccine.

**Table 57-3** COMMONLY ADMINISTERED IMMUNIZATIONS FOR INFANTS, ADOLESCENTS, AND ADULTS<sup>a</sup>

Vaccine	Vaccine Antigen	Target Population <sup>b</sup>	Number of Doses	Schedule
<b>Viral Vaccines</b>				
Hepatitis A (HepA)	Inactivated, whole virus	Children < 2 years <sup>c</sup>	2	12–24 months
Hepatitis B (HepB)	Recombinant, HBsAg subunit	All	3	Birth, 1–2 months, 6–18 months <sup>d</sup>
Human papillomavirus (HPV)	Viral subunits; HPV4, quadravalent, HPV2, bivalent	Adolescent females <sup>e</sup>	3	11–12 years
Inactivated polio (IPV)	Inactivated, whole virus <sup>f</sup>	Children < 5 years	4	2, 4, 6–18 months, 4–5 years
Influenza <sup>g</sup>	TIV, trivalent, inactivated; LAIV, live, attenuated, influenza	All, annually	2 for first use; single dose annually, thereafter	LAIV for use 2–49 years only; minimum age of 6 months for TIV
Measles, mumps, rubella	Live, attenuated, whole viruses	Children, < 5 years <sup>h</sup>	1, with 1 booster	15–18 months, 4–6 years
Rotavirus (live oral)	Live, attenuated virus	Infants < 6 months old	3	2, 4, and 6 months
Varicella	Live, attenuated, whole virus	Children, < 5 years; others at-risk	1, with 1 booster	15–18 months, 4–6 years
Zoster	Live, attenuated virus	> 60 years	1	> 60 years
<b>Bacterial Vaccines</b>				
Diphtheria, tetanus, pertussis (DTaP, Tdap for one-time adolescent and adult use <sup>i</sup> )	Diphtheria and tetanus toxoids, acellular pertussis containing 2–4 purified bacterial components	Infants and children, < 6 years; boost for adolescents and adults	5	2, 4, 6, 15–18 months, and 4–5 years
<i>Haemophilus influenzae</i> <sup>b</sup>	Type b-polysaccharide—protein conjugate, usually tetanus toxoid	Infants, children < 2 years	4	2, 4, 6, 12–15 months
Meningococcal	MCV4, 4-valent, polysaccharide conjugate; MPSV4, 4-valent, polysaccharide	Adolescents; also, certain “at-risk” populations <sup>j</sup>	1, with 1 booster	11–12 years, 16 years
Pneumococcal	PCV, 13-valent, pneumococcal polysaccharide conjugate; PPSV, 23-valent, pneumococcal polysaccharide <sup>k</sup>	Infants, children, adults > 65 <sup>l</sup> years		
Tetanus (Td)	Tetanus and diphtheria toxoids	All	3, with boosters	Every 10 years <sup>l</sup>

<sup>a</sup>The recommended immunizations and schedules are approved annually by the Advisory Committee on Immunization Practices (ACIP). Updates and complete schedules, including catch-up schedules and special indications for vaccination, can be found at <http://www.cdc.gov/vaccines/recs>.

<sup>b</sup>The entire target population is not listed in all cases.

<sup>c</sup>HepA is also recommended for older children at greater risk for hepatitis A infection.

<sup>d</sup>HepB can be administered as a “catch-up” vaccine for adolescents and adults.

<sup>e</sup>HPV may be administered as a catch-up vaccination for females up to age 26; HPV4 is recommended for administration to adolescent males.

<sup>f</sup>Live, attenuated, oral polio vaccine (OPV) is no longer used in the United States.

<sup>g</sup>Both TIV and LAIV are trivalent influenza vaccines, selected annually; certain medical conditions may preclude the use of LAIV.

<sup>h</sup>Additional two-dose series of MMR is recommended for adults in certain situations.

<sup>i</sup>Tdap should be substituted for Td one time for adolescents and adults.

<sup>j</sup>Younger children at risk may receive MCV4 at 2 years; MPSV4 is preferred for those > 55 years.

<sup>k</sup>Children < 2 years should receive the PCV13 vaccine; PPSV is recommended for adults.

<sup>l</sup>The pneumococcal vaccination is also recommended for adult smokers and those with certain medical conditions (e.g., asthma).

- c. **Seroconversion.** For many active vaccines, the success of the series of vaccinations is indicated by seroconversion of the patient. Seroconversion indicates that a person who previously did not have specific serum antibodies (i.e., seronegative) now has these antibodies (i.e., seropositive). Seroconversion does not necessarily indicate established immunity, especially in the case of live vaccines.
  - d. **A schedule of active vaccination.** Successful vaccination can be affected by the age of the patient; therefore, the timing of childhood immunizations is driven largely by the efficacy of the vaccine in the age population. Newborns have poorly developed immune systems and rely chiefly on passively acquired maternal antibodies for the first few months of life. With the exception of the hepatitis B vaccine, which is administered at birth, most immunizations are deferred until the child is 2 months old. The rotavirus vaccine is the only currently administered live, attenuated vaccine for use in infants. Some vaccines are intended for use primarily in noninfant populations.
  - e. Most vaccines require a **series of vaccinations** to achieve adequate immunity, whereas others are effective with a single vaccination. For those that require a series, intervals between vaccinations greater than those recommended do not generally diminish protection. The duration of memory varies with each vaccine, and **booster vaccinations** are often necessary.
  - f. **Side effects** include inflammation at the site of vaccination, malaise, mild fever, chills, headache, myalgia, and arthralgia. More severe side effects include febrile illness, somnolence, seizures, or anaphylactic hypersensitivity to vaccine antigens or accessory components (e.g., antibiotic, chicken protein). Severe reactions contraindicate continuation of a series.
2. **Types of active vaccines**
- a. **Live, attenuated vaccines** consist of whole organisms, usually viruses. These organisms multiply after vaccination but are attenuated to reduce their pathogenicity.
    - (1) A small dose produces a **strong, long-lasting immune response** because the antigen concentration increases when the organism multiplies. Some vaccines elicit lifelong immunity in one or two doses (e.g., the measles, mumps, rubella [MMR] vaccine).
    - (2) **Live, attenuated viral vaccines** are not recommended for pregnant women or those intending to become pregnant within 3 months of vaccination. Vaccines made from attenuated agents (e.g., MMR, varicella) have the potential for causing disease in immunocompromised patients and are generally not advised for use in these patient populations or those with other underlying illness.
  - b. **Inactivated vaccines** may contain whole, inactivated (killed) bacteria or viruses, or any antigenic fraction isolated from either. Fractional vaccines are either protein based or polysaccharide based. **Toxoids** (inactivated bacterial toxins) and **viral subunit vaccines** (e.g., hemagglutinin of influenza or capsid proteins of papilloma) are protein-based vaccines. The acellular pertussis vaccine is also a protein-based subunit vaccine, containing two or more antigens for *Bordetella pertussis*. Some subunit vaccines are produced by recombinant DNA technology typically in yeast cells (e.g., hepatitis B surface antigen, human papillomavirus [HPV] vaccine). Most polysaccharide vaccines are **capsular polysaccharide** antigens, which tend to elicit a poor immune response in children. **Conjugate polysaccharide vaccines** contain the capsular polysaccharide antigen, chemically linked to a protein carrier, which elicits a better immune response (e.g., *Haemophilus influenzae* type b). The *Neisseria meningitidis* and *Streptococcus pneumoniae* vaccines are both available as pure polysaccharide and polysaccharide conjugate vaccines.
    - (1) Inactivated vaccines are not able to replicate and **cannot cause disease** from infection, even in an immunodeficient person. Inactivated vaccines are typically safe to administer during pregnancy, with the exception of the HPV vaccine, which should not be administered during pregnancy.
    - (2) Inactivated vaccines **require multiple doses** and typically only produce humoral immunity. Antibody titer to inactivated vaccine antigens diminishes over time and may require periodic repeated vaccination to increase or “boost” antibody titers. Pure polysaccharide vaccines tend to be T-cell-independent antigens and often do not elicit a memory response that is boosted with subsequent doses.

- D. Simultaneous administration of active and passive vaccines.** Sometimes active and passive vaccines against a pathogenic organism are administered simultaneously to maximize postexposure prophylaxis. The immunoglobulin offers immediate protection, and the active vaccine stimulates a lasting immune response. These vaccines are given at separate sites to prevent antibody (passive) and antigen (active) from reacting and inactivating one another.
1. **HBV and HBIG.** Infants who are born to mothers with a hepatitis B infection are significantly protected from becoming chronic carriers by the combined prophylaxis.
  2. **Tetanus.** Combined prophylaxis is sometimes used, depending on the type of wound and the patient's history of active vaccination. Recommended guidelines are as follows:
    - a. **A tetanus-prone wound** is one that produces anaerobic conditions (e.g., deep puncture) or one in which exposure to *Clostridium* or its spores is probable (e.g., contaminated with animal feces). If the patient's history of active vaccination is uncertain or includes fewer than three doses, both TIG and Td are administered. The patient returns to complete the toxoid series.
      - (1) If the wound is tetanus-prone but the patient received a full series of active vaccination, no treatment is necessary if the last Td dose was received within the last 5 years.
      - (2) If the last dose was received more than 5 years ago, Td, but not TIG, is given to boost memory immunity and antibody production.
    - b. For a **clean, minor wound**, if the patient's history of active vaccination is uncertain or includes fewer than three doses, Td is administered.
      - (1) If the patient received a full series of active vaccinations, no treatment is necessary if the last Td dose was received within 10 years.
      - (2) If the last dose was received more than 10 years ago, Td, but not TIG, is given to boost memory immunity and antibody production.

## XI. IMMUNIZATION PRACTICE FOR THE PHARMACIST

- A. Background.** Since the 1970s, there has been a growing interest in using pharmacists for the administration of immunizations. In 1994, the secretary of U.S. Department of Health and Human Services sought the aid of the American Pharmacists Association to improve immunization rates in the United States. As a result, certificate programs were developed to ensure the knowledge and capabilities of pharmacists to administer vaccines. Currently, **all 50 states** offer some level of pharmacist-provided immunizations.
- B. Legal and regulatory issues**
1. **State law.** Although pharmacists are authorized to immunize in every state, the requirements to be authorized and the scope and restrictions on immunization practice vary from state to state. Please refer to your state's Pharmacy Practice Act to determine specifics. Limitations and requirements include education and/or certification requirements, age of patients who can be immunized, scope of vaccines allowed, CPR requirements, continuing education requirements, vaccine administration authorizations (prescription, collaborative practice agreements, protocols, standing orders), approved routes of administration, and student pharmacist provisions.
  2. **Liability issues.** Federal law requires that all patients immunized be provided with the most current **Vaccine Information Statement (VIS)** for the particular vaccine being given. These are available on the Centers for Disease Control and Prevention (CDC) Web site (<http://www.cdc.gov/vaccines>). It is paramount that the immunizing pharmacist stays within the state's Pharmacy Practice Act. Pharmacists may only offer vaccines that are on the state's list of vaccines approved for pharmacist administration and only to the designated age population.
  3. The pharmacist must have **adequate training to immunize** and keep that training up to date.
  4. **Vaccine Injury Compensation Program (VICP)** is a national program that protects manufacturers and providers (including pharmacists) from vaccine injury claims for adverse effects listed on the Vaccine Injury Table (see Web site at <http://www.hrsa.gov/vaccinecompensation/default.htm>) while maintaining a fund from which injury claims could be paid.

- C. Pharmacies that provide immunizations must adhere to **Occupational Safety and Health Administration (OSHA)** safety regulations to minimize risks to their employees and document compliance with each of the OSHA regulations.
1. OSHA regulations include required training regarding potential exposure to **blood-borne pathogens**, which must be provided at the outset of any immunization program, at the time an employee is assigned to immunization duties and annually thereafter. This training must be offered at no cost to the employee and during regular working hours.
  2. An employer must provide the **hepatitis B series** to any employee who will be at risk of exposure to blood-borne disease.
  3. OSHA requires the use of **needles, syringes, and/or safety devices** attached to needles and syringes to minimize injury with any such contaminated device.
  4. The employer is required to maintain a log of all incidents of percutaneous injury by contaminated sharp equipment. The log needs to list the type and brand of equipment involved, the area where the injury occurred, and a description of how it happened.
- D. **Vaccine storage and management.** Vaccines, like most biologicals, are sensitive to changes in temperature. All vaccines currently available in the United States must be stored under controlled temperature conditions, as described for each vaccine formulation.
- E. **Record keeping**
1. **Patient immunization records** should be maintained by the patient's medical provider; however, patients can benefit by pharmacists maintaining these records and providing a copy to the patient.
  2. **Vaccine administration record.** The immunizing pharmacist is required by the National Vaccine Injury Compensation Program to document and maintain certain information for all vaccines administered: administration date; vaccine manufacturer; lot number and expiration date; name, address, and title of administering pharmacist; and VIS—date printed on VIS and date given to patient.
  3. Vaccine administration records must be permanent and readily retrievable. They may be stored as paper files or electronically. The length of time these records must be kept may vary by state. Usually, however, records must be maintained for at least the life of the patient.
- F. **Vaccine resource materials for the immunizing pharmacist.** Immunization practice is a constantly changing field. New vaccines, changes in administration schedules, and adverse reaction alerts are only a few of the topics that require the pharmacist to maintain competence.
1. **Basic reference.** Centers for Disease Control and Prevention. *Epidemiology and Prevention of Vaccine-Preventable Diseases*. 12th ed. Washington, DC: Public Health Foundation; 2011. <http://www.cdc.gov/vaccines/pubs/pinkbook/default.htm>. Accessed May 12, 2011.
  2. **Web sites**
    - a. Centers for Disease Control and Prevention. Vaccines and Immunizations. <http://www.cdc.gov/vaccines>
    - b. Immunization Action Coalition. <http://www.immunize.org>
    - c. American Pharmacists Association. Pharmacist Immunization Center. [http://www.pharmacist.com/AM/Template.cfm?Section=Pharmacist\\_Immunization\\_Center1&Template=/TaggedPage/TaggedPageDisplay.cfm&TPLID=126&ContentID=20733](http://www.pharmacist.com/AM/Template.cfm?Section=Pharmacist_Immunization_Center1&Template=/TaggedPage/TaggedPageDisplay.cfm&TPLID=126&ContentID=20733)
- G. **Clinical issues**
1. **Identifying the patient's needs.** Determining the patient's vaccine needs requires an immunization history, which can be provided by the patient and possibly contacting the medical provider.
  2. **Screening the patient.** Each year, the Advisory Committee on Immunization Practices (ACIP) of the CDC reviews and updates the use of vaccines. Recommendations are published in schedules designated for particular populations (<http://www.cdc.gov/vaccines/recs/schedules/default.htm>). The ACIP guidelines for administration should be consulted to ensure the appropriate vaccine is administered.
  3. **Contraindications and precautions.** Contraindications are conditions that greatly increase the chance of an adverse reaction. According to the CDC, there are two permanent contraindications to vaccine administration: severe allergic reaction to a previous dose and encephalopathy occurring within 7 days of pertussis vaccination (for which no other cause is identified). Mild illness, current antimicrobial therapy, breastfeeding, and having a pregnant or immunosuppressed person living in the household are not considered to be valid contraindications. If, however, the patient describes symptoms for which you would normally refer to a physician, defer immunization until the illness resolves. Live vaccines and HPV should not be given to pregnant women, but deferred

till afterward. The tetanus, diphtheria, and acellular pertussis booster vaccine (Tdap) should also be deferred until the latter half of the pregnancy, whereas the standard tetanus and diphtheria booster (Td) can safely be given if needed during pregnancy. Live vaccines should not be given to severely immunosuppressed individuals. Inactivated vaccines may be given to people such as these, although response may be muted. Please refer to the CDC Web site for a more thorough discussion of precautions. When in doubt, refer the patient to a physician.

4. **Adverse events**
  - a. **Local reactions** at the injection site are most commonly seen following administration of inactivated vaccines. Patients should be advised to take an anti-inflammatory and/or apply a cool compress to control these symptoms.
  - b. **Systemic vaccine-related reactions** following live vaccine administration represent a mild form of the disease and are usually no cause for alarm. Patients experiencing a more severe response should be referred to their medical provider.
  - c. **Vasovagal syncope** is a temporary loss of consciousness that sometimes occurs following injections of any kind. Most occur within 15 mins of the injection and resolve quickly. Patients may complain of being dizzy or light-headed, may appear pale and sweaty, and have cold hands and feet. Occasionally, the patient may experience nausea. If affected, patients should be kept in a supine position with legs elevated. The blood pressure and pulse should be monitored. If blood pressure falls or the patient does not regain consciousness quickly, call 911. Because of the possibility of aspiration, water or other fluids should not be offered to a patient experiencing syncope.
5. **Allergic reactions** can occur within a few minutes or up to an hour after vaccination. Mild allergy can result in pruritis, erythema, hives, and urticaria. These symptoms can generally be controlled with antihistamines. If the patient does not respond to the antihistamine or if the condition continues to progress, the patient should immediately contact a medical provider. The patient should always report any allergic reaction to the primary care physician.
6. **Anaphylaxis** is a severe, life-threatening allergic reaction (see section VI.B.4.d) that requires immediate intervention (see next discussion) while summoning emergency care (911). Symptoms can include those seen in mild allergic reactions, but more importantly, include angioedema (swelling of the lips, tongue, and throat), bronchospasm, shortness of breath, and cramping. This often progresses to shock and cardiovascular collapse.
- H. **Emergency preparedness.** Procedures for handling emergency situations should be detailed in a policy and procedure manual and any standing order or protocol, including the use of emergency drugs. Any adverse reaction requiring a response should be reported via the **Vaccine Adverse Event Reporting System (VAERS)** available at <http://vaers.hhs.gov/index>.
  1. Patients should be advised to remain in an area where they can be observed for **15 mins** following vaccination.
  2. Because of the potential for syncope, the pharmacist should administer vaccines to patients who are sitting in an open area. This will allow the pharmacist to support the patient while he or she is being lowered to the floor.
  3. **Antihistamines** should be accessible in the event a patient begins to experience allergic reactions following immunization. Typically, diphenhydramine elixir 25 to 50 mg should be given orally at the first sign of symptoms.
  4. **Epinephrine** should be available for use in apparent anaphylaxis reactions. Vaccines should never be administered if epinephrine is not available. Multiple doses should be available in case of a delayed emergency medical services response.
    - a. **Dosage forms**
      - (1) Vial at 1:1000 w/v equivalent to 1 mg/mL
      - (2) Autoinjector
        - (a) Epi-pen 0.3 mg/pen
        - (b) Epi-pen Jr 0.15 mg/pen
    - b. **Dose**
      - (1) Vial: 0.01 mL/kg
      - (2) Autoinjector: 1 pen
    - c. **Route:** IM (preferred) has faster onset than SQ
    - d. Repeat every 5 to 15 mins if needed

# Study Questions

**Directions:** Each question, statement, or item in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

- A man was ill 10 days ago with a viral illness. Laboratory analysis of the patient's blood reveals that the patient's antiviral antibodies have a high ratio of IgM/IgG. What does this tell you?
    - It is unlikely that the patient had encountered this virus before his recent illness.
    - The patient is predisposed to IgE responses to this virus.
    - This information is unrelated to the recent viral illness.
    - This patient's response is due to a memory response.
    - It is likely that this patient is developing an autoimmune disorder.
  - Which class of antibody has the longest serum half-life and opsonizes antigens for phagocytosis through two different pathways?
    - Immunoglobulin A (IgA)
    - Immunoglobulin D (IgD)
    - Immunoglobulin E (IgE)
    - Immunoglobulin G (IgG)
    - Immunoglobulin M (IgM)
  - Urticaria that appears rapidly after the ingestion of food usually indicates which type of hypersensitivity reaction?
    - Type I
    - Type II
    - Type III
    - Type IV
  - The mechanism of pathogenesis for which of the following autoimmune disorders is due to widely distributed immune complexes?
    - Systemic lupus erythematosus (SLE)
    - Insulin-dependent diabetes mellitus (IDDM)
    - Graves disease
    - Hashimoto thyroiditis
    - Multiple sclerosis
  - A patient receives long-term, high-dose therapy with penicillin. After approximately 2 weeks of therapy, the patient has a low-grade fever, rash, and muscle and joint pain. Which type of hypersensitivity accounts for these symptoms?
    - Type I
    - Type II
    - Type III
    - Type IV
    - This is unlikely to be due to a hypersensitivity
  - The treatment of multiple sclerosis (MS) might include which of the following agents?
    - Neostigmine
    - Cyanocobalamin
    - Omalizumab
    - Propylthiouracil
    - IFN- $\beta$ -1b
  - The therapeutic role of muromonab-CD3 in acute renal graft rejection is probably based on
    - activation of T-cell function and increased secretion of cytokines.
    - destruction of T cells by complement.
    - opsonization of T cells for phagocytosis.
    - apoptosis of activated T cells.
    - activation of T<sub>REG</sub> cells.
  - Which is a current clinical application of intravenous human immunoglobulin (IVIG)?
    - Prophylaxis after hepatitis B virus (HBV) exposure
    - Treatment of humoral immunodeficiency
    - Prophylactic infant immunization for respiratory syncytial virus (RSV)
    - Prophylaxis for Rh disease by infant immunization
    - Treatment for snake bites
- For questions 9 and 10:** An 18-year-old college student has a deep puncture wound. The student is unsure of his history of vaccination.
- If no other information is available, what should the physician recommend?
    - No vaccination
    - Tetanus immunoglobulin (TIG)
    - Tetanus toxoid (Td)
    - Both TIG and Td at separate sites
    - Administer IVIG and Tdap

10. If the student had received a full series of diphtheria, pertussis, tetanus (DTaP) vaccinations as a child, and received the Tdap prior to entry into college last year, what should the physician recommend?
- No vaccination
  - Tetanus immunoglobulin (TIG)
  - Tetanus toxoid (Td)
  - Both TIG and Td at separate sites
  - Administer IVIG and Tdap
11. CD4<sup>+</sup> T cells specifically recognize antigens in which form?
- Bound to major histocompatibility complex (MHC) class I molecules on the surface of any nucleated cell
  - In free, soluble form in extracellular fluids
  - Bound to MHC class II molecules on the surface of special antigen-presenting cells (APCs)
  - Bound to complement receptors on professional antigen-presenting cells (APCs)
  - Associated with class II MHC on the surface of T<sub>C</sub> cells
12. The normal consequence of complement activation by either the lectin or alternative pathway includes all of the following EXCEPT?
- Acute inflammation
  - Immune complex clearance
  - Cytolytic action
  - Recruitment of leukocytes
  - Opsonization of microbes
13. In antiviral immunity, what directly recognizes and kills viral-infected cells?
- Complement
  - Antiviral antibodies
  - Interferons
  - Eosinophils
  - Cytotoxic T cells (CTLs)
14. A patient was skin tested with purified protein derivative (PPD), which was administered to determine previous exposure to *Mycobacterium tuberculosis*. The patient developed redness and induration at the skin test site 48 hrs after inoculation. Histologically, the reaction at this site would most probably show
- plasma cell infiltration.
  - eosinophils.
  - neutrophils.
  - acid-fast bacilli.
  - T cells and macrophages.
15. Graft versus host disease (GVHD) is associated primarily with which type of transplantation?
- Kidney
  - Heart
  - Bone marrow
  - Cornea
  - Autografts
16. The prophylactic use of cyclosporine in graft rejection is probably based on its ability to
- competitively inhibit the IL-2 at the IL-2 receptor.
  - inhibit synthesis of antibodies, thereby preventing hyperacute rejection.
  - inhibit activation of B cells, thereby preventing acute rejection.
  - block transcription of the IL-2 gene and synthesis/secretion of IL-2.
  - induce apoptosis in activated T cells.
17. Which statement about pneumococcal and meningococcal vaccines is true?
- They are both available as a purified polysaccharides or conjugated polysaccharide.
  - They are both recommended for children < 2 years of age.
  - Each vaccine formulation contains all serotypes of disease-causing organisms.
  - They are live attenuated, requiring only a single dose to be effective.
  - They should not be administered during pregnancy.
18. A patient currently taking methyl dopa develops hemolytic anemia, which resolves shortly after the drug is withdrawn. The most probable explanation is that the patient was experiencing
- an atopic hypersensitivity.
  - a type II hypersensitivity.
  - immune complex hypersensitivity.
  - cell-mediated hypersensitivity.
  - a type IV hypersensitivity.
19. Infliximab (Remicade) is a chimeric monoclonal antibody that binds directly to TNF- $\alpha$ . Patients taking this medication should be advised that they are
- more susceptible to infections because TNF- $\alpha$  is important for synthesizing IgM.
  - more susceptible to infections because they will generate more lymphocytes in the absence of TNF- $\alpha$ .
  - less susceptible to infections because T<sub>H</sub>1 responses will predominate in the absence of TNF- $\alpha$ .
  - more susceptible to infections because the initiation of inflammation will be less efficient without TNF- $\alpha$ .
  - less susceptible to infections because they will not initiate an acute-phase response without TNF- $\alpha$ .

20. What would be the typical time frame for the appearance of a type IV hypersensitivity reaction in a person already sensitized to the antigen?
- (A) Within a few minutes
  - (B) Within a few hours
  - (C) Within a few days
  - (D) Within a few weeks
  - (E) Within a few months
21. For a patient who was experiencing a type I hypersensitivity, including difficulty breathing and loss of consciousness, which of the following would be the most appropriate medical intervention?
- (A) injection of epinephrine
  - (B) injection of nonsteroidal anti-inflammatory drugs
  - (C) injection of antihistamines
  - (D) injection of corticosteroids
  - (E) administer an oral H<sub>2</sub>-receptor inhibitor

## Answers and Explanations

**1. The answer is A [see IV.B].**

The primary immune response to an infection is characterized by the initial production of IgM beginning 4 to 6 days and peaking 9 to 14 days after introduction of the antigen. Under the influence of T<sub>H</sub> cells, activated B cells will undergo isotype switching to produce antibodies that might be more effective (e.g., IgG, longer lasting, opsonic, distributed well in tissues; IgA, high concentrations in mucous; IgE, parasitic infections and mast cell activation). Memory responses maintain the isotype effective from the previous immune response.

**2. The answer is D [see IV.F.2.c].**

IgG has the longest lasting serum half-life (21 days for most subclasses) and is the most plentiful antibody in the serum. Antigen bound by IgG is opsonized for phagocytosis by neutrophils and macrophages via phagocyte Fc receptors; however, IgG is also able to activate complement, which will lead to the addition of covalently bound C3b to the microbe surface. C3b is also an opsonin for which phagocytes have receptors that will assist with phagocytosis.

**3. The answer is A [see VI.B.4.c].**

Food allergies are usually type I reactions. In a patient with mast cells already associated with IgE specific to a food allergen, the allergic response usually occurs shortly after ingestion. Mast cell activation and degranulation in the gastrointestinal tract leads to smooth muscle contraction (vomiting) and increased mucous and acid secretion. Allergen absorbed into the circulation may lead to mast cell degranulation in the skin (e.g., urticaria) or anaphylaxis.

**4. The answer is A [see VII.C.3].**

In SLE, persistent circulating immune complexes (typically containing nuclear antigens, such as nucleoproteins and nucleic acids) are responsible for much of the pathology. In Graves disease, an antibody acting as a TSH agonist hyperstimulates the thyroid. In IDDM,

T-cell cytotoxicity, and potentially antibody production, leads to the destruction of the beta islet cells in the pancreas. In Hashimoto thyroiditis, antibodies and CTLs (and macrophages) infiltrate the thyroid. With multiple sclerosis, T<sub>H</sub>1 cells and the resulting inflammatory responses are thought to be responsible for the demyelination.

**5. The answer is C [see VI.D.2].**

One of the most common causes of a type III hypersensitivity reaction is the response to drugs, often when they are used long term at a high dose and delivered intravenously. The treatment is to discontinue the drug.

**6. The answer is E [see VII.B.8].**

Treatment with IFN- $\beta$ -1b reduces the frequency of MS flare-ups. The precise mechanism of action is currently unknown but may involve the activation of suppressor T cells and reduced production of proinflammatory cytokines. Neostigmine is used as an anticholinergic agent in myasthenia gravis. Cyanocobalamin is administered in autoimmune pernicious anemia to replace nonabsorbed vitamin B<sub>12</sub>. Propylthiouracil is used as an antithyroid medication in Graves disease. Omalizumab is a monoclonal antibody that targets IgE.

**7. The answer is C [see X.B.2.d].**

Muromonab-CD3 is a mouse anti-CD3 monoclonal antibody that binds to all T cells because CD3 is a constant part of the antigen receptor of each T cell. The binding of muromonab-CD3 opsonizes the T cells for phagocytosis, chiefly in the liver, and the overall effect is a reduction in the total number of T cells. A later secondary phase of activity seems to involve antigenic modulation of the T cells such that the CD3 is removed from the surface, rendering those T cells incapable of signaling antigen binding. Mouse antibodies are inefficient at activating human complement. Some T-cell activation with cytokine secretion occurs, but it is an undesirable side effect of muromonab-CD3 administration.

**8. The answer is B** [see X.B.1.b; Table 57-2].

IVIGs are used to replace antibodies in immunodeficient individuals. Each of the other choices is a formulation of passive transfer of antibodies; however, they are either enriched for specific antibodies or monoclonal antibodies (in the case of the RSV prophylaxis). Hepatitis B immunoglobulin (HBIG) is administered intramuscularly. Anti-Rh antibody is also administered intramuscularly to the mother immediately postpartum (sometimes during pregnancy) but not to the infant. Snake bite antivenin is derived from sera produced in horses.

**9. The answer is D** [see X.D.2.a].

A patient with an uncertain history of vaccination and a tetanus-prone wound requires both active and passive vaccination. TIG provides immediate protection if the individual does not have memory. Td begins the series that leads to the establishment of memory. A tetanus-prone wound in an individual with a full series of active vaccinations requires no treatment if the last vaccination in the series was administered less than 5 years earlier. These recommendations are general guidelines.

**10. The answer is A** [see X.D.2.a.(1)].

Even if the wound is a tetanus-prone wound, booster vaccination within 5 years obviates the need for additional tetanus vaccination.

**11. The answer is C** [see I.B.6.b.(1).(b)].

CD4<sup>+</sup> (helper) T cells have TCRs that recognize fragments (epitopes) of immunizing antigens (immunogens) only when the peptide fragments are bound to MHC class II molecule on the surface of APCs (B cells, macrophages, or dendritic cells). CD8<sup>+</sup> T cells recognize peptide fragments bound to MHC class I molecules. As a result, T cells cannot be activated inappropriately by soluble antigens.

**12. The answer is B** [see II.D.2.d].

The four functions of complement are inflammation, opsonization, cell lysis, and immune complex clearance. The classical pathway of complement activation is responsible for immune complex clearance because the antibody associated with the complexes initiates the classical pathway. When complement is activated, regardless of the pathway of activation, the complement components have functions that lead to all three of the other actions. Acute inflammation allows greater movement of plasma proteins and phagocytes from blood to tissue. Opsonization of immune complexes enhances their phagocytosis. Cytolysis of microorganisms by the membrane attack complex often results in their killing.

**13. The answer is E** [see III.B.2.b].

Antiviral antibodies are important in extracellular immunity to viruses by neutralizing them for infection of additional cells and targeting the viruses for opsonization by complement. Interferons are secreted from viral-infected and other cells (e.g., macrophages, T cells) and, after binding to receptors, induce the appearance of antiviral proteins in other cells. CTLs recognize viral-infected cells and cause direct cytotoxicity.

**14. The answer is E** [see VI.E.1].

Type IV hypersensitivity reactions are delayed after the introduction of antigen because antigen-specific T cells become activated and attract other cells, such as macrophages, to the site of antigen introduction (e.g., the epidermis of the skin in contact sensitivity, the lungs in tuberculosis). Inflammation is primarily caused by tissue damage and secretion of proinflammatory cytokines by the infiltrating cells. Although histamine release from local mast cells can also occur, H<sub>1</sub>-antagonists of histamine usually do not have significant effects because T cell and macrophage activation, migration, and secretion are not greatly affected by these drugs.

**15. The answer is C** [see IX.D].

In bone marrow transplantation, marrow containing mature lymphocytes is transplanted to a generally immunosuppressed host. The greatest problem is an immune response by the graft lymphocytes against HLA and other tissue antigens of the host. In renal and cardiac transplantation, the greatest problem is rejection of the foreign organ by the immune system of the host. Corneal transplants do not elicit rejection nor do autograft transplants (transplants from one part of the body to another on the same individual).

**16. The answer is D** [see III.A].

Cell-mediated immune mechanisms are central in acute graft rejection, and the inhibition of T-cell activation appears to be the key element in immunosuppression. Responding T cells require signaling from IL-2 to reach full activation and progress to cell division. IL-2 is produced by activated T cells and can act in an autocrine manner. Cyclosporine blocks the cascade of signals that occur when T cells encounter specific antigen. The T-cell signaling is important for the transcription of the IL-2 gene. Inhibiting those signals inhibits the synthesis of IL-2 and prevents full T-cell activation and division. Its effects are limited to activated T cells. Because it has no direct effect on antibody synthesis, it is not useful in the hyperacute rejection phenomena, which is based on antibody-mediated mechanisms. Hyperacute rejection is essentially untreatable because it depends on the presence of antibodies in the graft recipient.

**17. The answer is A** [see X.C.2.b; Table 57-3].

The pneumococcal and meningococcal vaccines are multivalent and contain purified polysaccharide (PPSV23 and MPSV4, respectively) from a number of different serotypes (indicated by the number associated with each vaccine designation above). However, these vaccines do not contain polysaccharide from all of the relevant infectious agents. The pneumococcal and meningococcal vaccines are also formulated as a conjugate vaccine (MCV4 and PCV13, respectively). The pneumococcal vaccine is recommended for infants and children, beginning at 2 months. The minimum age for administration of the meningococcal vaccine is 2 years, although the recommended age dosing is 11 to 12 years.

**18. The answer is B** [see VI.C.1].

This patient was experiencing a type II hypersensitivity reaction, which is characterized by antibody-mediated lysis of host cells (in this case, erythrocytes) due to the presence of exogenous antigen (methyldopa). An atopic hypersensitivity (type I, IgE mediated) would have exhibited atopic symptoms, such as urticaria. Immune complex hypersensitivity symptoms would include a skin rash, fever, and joint pain.

**19. The answer is D** [see Table 57-1].

TNF- $\alpha$  is involved in inflammation and T<sub>H</sub>1 responses. Inflammation is particularly important for responses to bacterial infections. Infliximab is prescribed for a number of autoimmune disorders that involve inflammatory mechanisms.

**20. The answer is C** [see VI.E].

Type IV hypersensitivity reactions are mediated by T cells (T<sub>H</sub>1, T<sub>H</sub>2, and CTL) and the inflammation associated with the T-cell activity. As such, the recruitment of the T cells typically takes 48 to 72 hrs after the introduction of the antigen. The classic example of a type IV hypersensitivity reaction is the tuberculin skin test.

**21. The correct answer is A** [see VI.B.6.e].

Many of the interventions will act on the allergic responses associated with a type I hypersensitivity reaction; however, this patient is experiencing a severe reaction. Epinephrine more immediately reverses the airway constriction.

# Principles of Pharmacology and Medicinal Chemistry

S. THOMAS ABRAHAM, MICHAEL L. ADAMS

**I. INTRODUCTION.** A complete understanding of the pharmacological actions of drugs requires an appreciation of their pharmacokinetic and pharmacodynamic properties, as well as the complexity of the biological responses modulated by these agents. This chapter will focus on the pharmacodynamic aspect of drugs with an emphasis on the mechanisms and consequences of drug-receptor interactions. Additionally, the chemical characteristics of pharmacological agents that influence their interactions with specific receptors will be addressed.

**II. RECEPTORS.** Currently, we understand that receptors are unique protein or glycoprotein structures that are responsible for the reception and transmission of information that ultimately alters the behavior of cells, organs, or even the entire organism. It is generally understood that endogenous hormones, neurotransmitters, or growth factors interact with specific receptors to modify cellular behavior.

**A. Cell surface receptors and their signal transduction**

1. **The seven transmembrane G protein-coupled receptors** are localized in the plasma membranes of cells in such a manner as to have seven transmembrane domains, with multiple extracellular and intracellular domains. This group of receptors is the most heterogeneous of the cell surface receptors and communicates with intracellular components by activating specific guanine nucleotide-binding (G) protein intermediates.

a. **G<sub>s</sub>-coupled receptors** (e.g.,  $\beta$ -adrenergic, vasopressin V2, glucagon, dopamine D1). These receptors are functionally coupled to adenylyl cyclase, which catalyzes the conversion of adenosine triphosphate (ATP) to cyclic adenosine monophosphate (cAMP), an intracellular second messenger (*Figure 58-1*). cAMP is responsible for the downstream activation of protein

**Figure 58-1.** The cAMP-PKA signaling system is responsible for diverse biological effects such as increased heart rate/contractility, vasodilation, and neurotransmitter release. *Epi*, epinephrine; *G<sub>s</sub>*, guanine nucleotide-binding protein; *ATP*, adenosine triphosphate; *cAMP*, cyclic adenosine monophosphate; *PKA*, protein kinase A.

**Figure 58-2.** The phosphoinositide signaling system is responsible for physiological responses such as salivary secretion, smooth muscle contraction, and hormone release. *ACh*, acetylcholine; *G<sub>q</sub>*, guanine nucleotide-binding protein; *PLC*, phospholipase C; *IP<sub>3</sub>*, inositol trisphosphate; *DAG*, diacylglycerol; *PKC*, protein kinase C; *PIP<sub>2</sub>*, phosphatidylinositol biphosphate.

kinase A (PKA), a multifunctional enzyme that alters the function of multiple substrates to ultimately produce effects such as increases in heart rate, release of glucose from the liver, decrease water loss in the kidneys, and increase neurotransmitter release.

- b. **G<sub>q</sub>-coupled receptors** (e.g.,  $\alpha_1$ -adrenergic, muscarinic M1, angiotensin AT1). Binding of endogenous ligands such as norepinephrine or acetylcholine leads to conformational change in the relevant receptor and activation of the associated G<sub>q</sub> protein, which in turn activates a membrane-bound phospholipase C. This enzyme catalyzes the hydrolysis of membranous phosphatidylinositol biphosphate (PIP<sub>2</sub>) resulting in the production of inositol trisphosphate (IP<sub>3</sub>) and diacylglycerol (DAG). The hydrophilic IP<sub>3</sub> releases stored calcium from the sarcoplasmic reticulum, whereas DAG activates protein kinase C (Figure 58-2). These processes are eventually responsible for biological processes such as smooth muscle contraction, aldosterone release, salivary secretion, etc.
  - c. **G<sub>i/o</sub>-coupled receptors** (e.g., muscarinic M2,  $\alpha_2$ -adrenergic, opioid). The best characterized results of activating receptors coupled to G<sub>i/o</sub> proteins is the decrease in intracellular cAMP and opening of K<sup>+</sup>-channels leading to hyperpolarization. The overall response of these types of events is inhibitory and leads to responses such as decreasing heart rate and inhibition of neurotransmitter release.
2. **Ion channels** found on the membranes of excitable cells (cardiac muscle, nerve cells, etc.) are important regulators of cellular function and serve as targets for pharmacological intervention.
    - a. **Ligand-gated channels** (e.g., nicotinic, GABA<sub>A</sub>, glutamate). The binding of endogenous ligands (acetylcholine, GABA, etc.) on the extracellular domains allows the opening of ion-selective pores on the protein that allow for the movement of ions such as sodium, chloride, or calcium. Depending on the ion being conducted, the eventual physiological response may be skeletal muscle contraction, nerve depolarization, or hyperpolarization.
    - b. **Voltage-gated channels** (e.g., calcium, sodium, potassium channels). Depolarizing currents lead to opening of these channel proteins, allowing the selective movement of specific ions into (calcium, sodium) or out (potassium) of the cell. These ion fluxes lead to cell depolarization (calcium, sodium) or repolarization (potassium) in a coordinated fashion to regulated muscle contraction and nerve action potential.
  3. **Growth factor receptors** (e.g., epidermal growth factor [EGF] receptor, insulin receptor, fibroblast growth factor receptor, interleukin-2 receptors). Generally, these receptors are composed of a single transmembrane domain containing a cytoplasmic tyrosine kinase. Thus, binding of EGF to its receptor results in receptor dimerization, activation of the tyrosine kinase motif, followed by cross phosphorylation of their cytoplasmic tail regions. This tyrosine phosphorylation on specific sequences serves to produce src-homology binding domains for the docking of additional proteins that transduce the signal to the interior of the cell. Consequently, EGF receptor activation leads to recruitment of Grb/Sos to the receptor with subsequent activation of the extracellular signal-regulated kinase (ERK) pathway to promote cell growth/replication (Figure 58-3). Similarly, insulin binding and receptor activation promotes insulin receptor substrate 1/2 (IRS-1/IRS-2) recruitment that increases plasma membrane glucose transporter expression and enhanced glucose uptake.

**Figure 58-3.** The ERK-MAPK signaling pathway mediates the biological processes of growth and differentiation. *EGF*, epidermal growth factor; *MEK*, ERK-kinase; *ERK*, extracellular signal-regulated kinase.

4. **Membrane transporters, pumps, and miscellaneous receptors** (e.g.,  $\text{Na}^+/\text{K}^+$ -ATPase, MDR-1 protein, natriuretic factor receptors). The natriuretic peptide family of proteins activates membrane-bound, single-transmembrane domain receptors that contain cytoplasmic guanylyl cyclase activity. Membrane-bound pumps such as the  $\text{Na}/\text{K}$ -ATPase and the MDR-1/P-glycoprotein are also targets for various therapeutic interventions even though they do not have well-characterized endogenous ligands.
- B. Intracellular receptors**
1. **Cytoplasmic receptors** may be as diverse as glucocorticoid hormone receptor, soluble guanylyl cyclase, and other enzymes or proteins that serve as targets for drugs (e.g., HMG-CoA reductase, tubulin, or calcineurin). The steroid receptors in this group (e.g., glucocorticoid receptor) have cytoplasmic localization until complexed to corticosteroids at which time they are translocated to the nucleus to function as transcription factors for gene expression (*Figure 58-4*).
  2. **Nuclear receptors** include those for thyroid hormone, sex steroids, retinoids, and peroxisome proliferator activator receptors. The binding of specific hormones to their respective receptors produces a complex that serves as transcription factors to modulate gene expression. Additionally, DNA and components of the nucleosome may serve as binding sites for specific drugs.
- C. Microorganism proteins as drug targets.** Various fungal, bacterial, and viral proteins (e.g., cell wall transamidase, fungal CYP450, viral thymidine kinase) are targeted for selective pharmacological intervention to treat relevant infections. These targets are often critical to the integrity or replication of the microorganism and their modulation can result in diminished viability of the infecting agent. Drug selectivity for these targets is achieved because they are structurally the distinction from analogous mammalian targets, and this often results in complete destruction of the offending microorganism.

### III. DRUG-RECEPTOR INTERACTIONS

- A. Drug-receptor binding.** At a fundamental level, drug molecules interact with specific receptors in order to produce the ultimate pharmacological effect. This interaction may be governed by the formation of hydrogen, ionic, or van der Waals bonds between given drug-receptor pairs. In general,

**Figure 58-4.** Signaling by hormones such as cortisol occurs via a cytoplasmic receptor that promotes specific gene expression after binding the ligand.

**Figure 58-5.** The binding of a drug to its receptor follows a rectangular hyperbolic relationship where the  $K_D$  is the concentration at which half the receptors are occupied. The  $B_{max}$  is the maximum number of binding sites (receptors) available to the drug and may be expressed in units such as moles/gram tissue.

these types of bonds are relatively weak and allow for the dissociation of the drug from the receptor, and the eventual pharmacological effect is reversed as the drug concentration at the receptor decreases. The tendency of drugs to bind to receptors is determined by its affinity for the receptor site as well as its concentration at that site, according to the law of mass action. Accordingly, the number of receptors  $[R]$  occupied by a drug depends on its concentration  $[D]$  and the drug–receptor association ( $k_1$ ) and dissociation ( $k_2$ ) rate constants such that

This equation suggests that the number of receptors bound by the drug at equilibrium is proportional to the concentration of the drug and is represented by a rectangular hyperbola (Figure 58-5). The ratio of  $k_2$  to  $k_1$  is better known as the **dissociation constant ( $K_D$ )** and represents the concentration of drug required to occupy 50% of the receptor sites in a tissue (Figure 58-5). The inverse of the  $K_D$  is equivalent to the **affinity** of a drug for its receptor and is proportional to the potency of the drug (below). Some drugs interact with their receptors by the formation of covalent bonds or dissociate so slowly from the receptor (very small  $k_2$ ) that the drug–receptor binding is irreversible or pseudo-irreversible at equilibrium. It could be expected that these types of drugs would have longer durations of action than those that are more rapidly reversible.

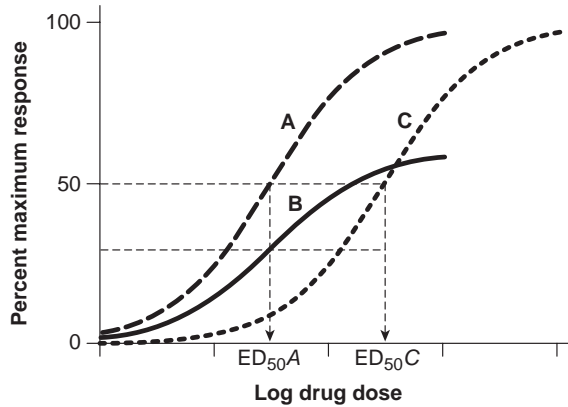

- B. Drugs as agonists.** Drugs that possess affinity for a specific receptor as well as intrinsic activity at that receptor are termed *agonists*. Agonists mimic the actions of the endogenous ligand (e.g., epinephrine for the  $\beta$ -adrenergic receptor) by modifying the conformation of the receptor in a manner that results in the initiation of intracellular signaling events and a biological response. Thus, dobutamine is able to mimic the actions of epinephrine at the  $\beta$ -receptor, producing increases in rate and contractility of the myocardium. For an agonist, Equation 58-1 can be modified to

The consequence of drug–receptor complex formation is a biological response that is proportional to the number of complexes formed. The application of increasing doses of an agonist will produce increasing biological response until a maximum effect is achieved. This relationship is represented by a sigmoidal dose–response curve when drug dose is plotted on a logarithmic scale (Figure 58-6).

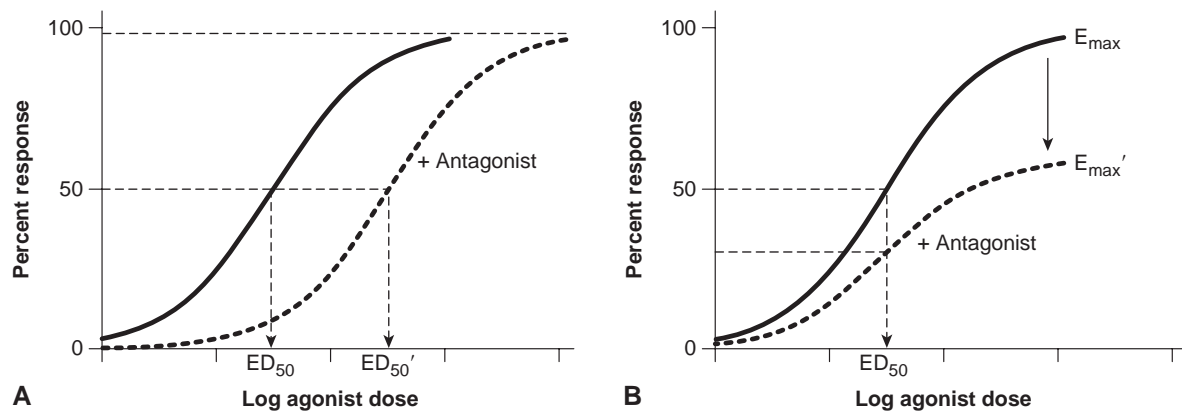

- 1. Full agonists** are able to produce increasing biological response with increasing dose until a maximal effect or efficacy ( $E_{max}$ ) is achieved, represented by a dose–response relationship (Figure 58-6). From this relationship, the effective dose that produces 50% of the  $E_{max}$  ( $ED_{50}$ ) can be determined as shown in Figure 58-6. The  $ED_{50}$  is a measure of the potency of the agonist such that drug A is more potent than drug C, even though the two have similar  $E_{max}$ s. Epinephrine is a full agonist at the  $\beta$ -receptor.

**Figure 58-6.** For the dose–response curves of three agonists, it can be seen that the A and C can be classified as full agonists because they are able to produce the maximal response possible, whereas B has a lower maximum, indicating a lower efficacy. However, agonist B has a greater potency than drug C because its  $ED_{50}$  is lower than that of C.  $ED_{50A}$ : dose of A producing 50% of its maximal response.

2. **Partial agonists** possess reduced intrinsic activity or efficacy, which results in reduced  $E_{max}$  relative to a full agonist (drug B versus drug A or C, *Figure 58-6*). However, a partial agonist may have greater affinity for the receptor, resulting in greater potency than a full agonist (compare drug B and C, *Figure 58-6*). Oxymetazoline (Afrin®) and buprenorphine (Buprenex®) are partial agonists at the  $\alpha$ -adrenergic and  $\mu$ -opioid receptors, respectively.
- C. Drugs as antagonists.** Drugs with affinity for a receptor but lacking intrinsic activity are called **antagonists**. These drugs are unable to alter receptor conformation in a way that leads to initiation of intracellular signal transduction processes and have their predominant pharmacological action by preventing the binding and actions of an endogenous ligand. Thus, atropine binds to the muscarinic receptor with high affinity but is unable to initiate a biological response; on the other hand, by occupying the binding site, it prevents the ability of acetylcholine to bind and produce an effect.
1. **Equilibrium-competitive antagonists** reversibly interact with the same binding site on the receptor as the agonist to prevent agonist binding and activation of the receptor. The reversibility of antagonist binding (*Equation 58-1*) allows the increasing doses of **agonist** to displace the antagonist to eventually produce the maximal biological response but with an apparent decrease in the affinity (increased  $ED_{50}$ ). On an agonist dose–response curve, the effect of equilibrium-competitive antagonists would be to shift the agonist curve to the right without a change in the maximal response (*Figure 58-7A*). Atropine is an example of an equilibrium-competitive antagonist at the muscarinic receptor.

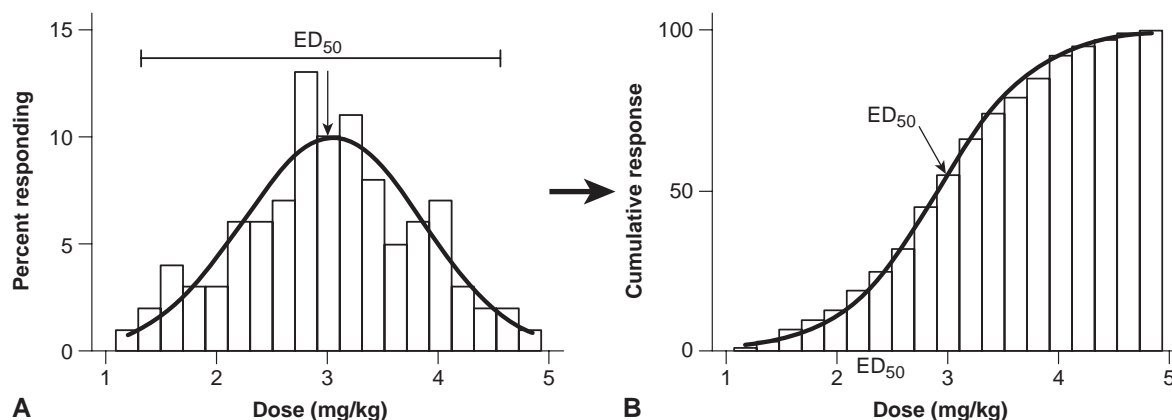

**Figure 58-7.** **A.** The apparent decrease in agonist potency (increase in the  $ED_{50}$  to  $ED_{50}'$ ; *dashed line*) in the presence of the antagonist without a decrease in the maximal response is indicative of an equilibrium-competitive antagonist. **B.** The decrease in the maximal response of the agonist curve after antagonist treatment (*dashed line*) would suggest the actions of a nonequilibrium or irreversible antagonist.

2. **Nonequilibrium-competitive antagonists** interact with their receptors in an irreversible or pseudo-irreversible manner, resulting in a very small  $k_2$  (Equation 58-1). This irreversibility (usually due to covalent bonding) would reduce the number of receptors available to produce a biological response, which results in an agonist dose–response curve with reduced  $E_{\max}$  and variable effect on potency (Figure 58-7B). Phenoxybenzamine (Dibenzylin<sup>®</sup>) is an example of nonequilibrium-competitive antagonist at the  $\alpha$ -adrenergic receptor.
  3. **Inverse agonists/antagonists** reduce the basal coupling of the receptor to the intracellular signal transduction processes, producing a negative pharmacological effect even in the *absence* of receptor agonists.  $\beta$ -Blockers like propranolol (Inderal<sup>®</sup>) are examples of drugs with both equilibrium-competitive antagonist and inverse agonist activity.
  4. **Noncompetitive antagonists** interact with a distinct site to that occupied by the agonist to prevent the biological response initiated by the agonist. This distinct site may be on the receptor itself (tyrosine kinase domain of the EGF receptor) or a downstream signaling molecule from the receptor (calcineurin in T-cell receptor signaling). The binding of the antagonist for its site cannot be displaced by increasing doses of agonist because there is no overlap in the two sites—there is no competition between the two ligands for a common site. Thus, erlotinib (Tarceva<sup>®</sup>) is a non-competitive antagonist of EGF at the EGF receptor and would reduce the efficacy of the agonist ( $E_{\max}$ ) to stimulate cell growth.
- D. Enzymes as drug receptors.** In many instances, cellular enzymes behave similarly to classical receptors in their interaction with drug molecules via ionic, hydrogen, van der Waal's, or covalent bonding. However, important differences in the behavior of enzymes warrant separate treatment.
1. **Competitive enzyme inhibitors** are drugs that bind to the active site of an enzyme in a manner that prevents substrate binding and conversion to a product. Analogous to classical drug-receptor interactions, these inhibitors would be considered competitive regardless of whether drug binding was reversible or irreversible. The inhibition of HMG-CoA reductase by simvastatin (Zocor<sup>®</sup>) would be considered competitive with respect to the substrate HMG-CoA.
    - a. **Transition-state inhibitors** mimic the transition state of the enzyme substrate having the highest free energy of activation and thus a high binding affinity for the substrate/active site (e.g., captopril [Capoten<sup>®</sup>] for the angiotensin-converting enzyme).
    - b. **Suicide enzyme inhibitors** are drugs that are catalyzed or destroyed in the process of binding to the active enzyme site; for example, neostigmine (Prostigmin<sup>®</sup>) is metabolized to a carbamate intermediate that covalently binds to the active site of acetylcholinesterase.
  2. **Allosteric modulators** bind to a distinct site from that of the substrate and thereby alter enzyme activity. Theoretically, this type of modulation can increase or decrease enzyme activity and not automatically be classified as inhibition. Allosteric modulators that inhibit enzyme activity may be considered noncompetitive inhibitors; for example, efavirenz (Sustiva<sup>®</sup>) inhibits the polymerase function of HIV reverse transcriptase.
- E. Modulation of receptor sensitivity**
1. **Desensitization** of seven transmembrane-spanning receptors generally occurs with sustained stimulation of the receptor and occurs due to reduced coupling to G proteins. Uncoupling of the receptor is due to phosphorylation of the receptor, which prevents its interaction with the G protein and also reduces the affinity of the agonist for the receptor. Myocardial  $\beta$ -receptors in patients with heart failure are thought to be desensitized due to sustained sympathetic nervous system stimulation.
  2. **Downregulation** of the receptor is the result of prolonged receptor stimulation that leads to incorporation of the receptor into clathrin-coated pits and removal of the receptor from the plasma membrane. This process reduces agonist signaling to the intracellular compartment. Ultimately, the receptor may be transported to the lysosomal compartment for destruction or recycled back to the plasma membrane to restore cell signaling. The sustained use of  $\beta$ -agonists like albuterol (Ventolin<sup>®</sup>) causes the downregulation of  $\beta_2$ -receptors in asthmatic patients.
  3. **Receptor hypersensitivity/supersensitivity** is exhibited by increased response to agonist stimulation and is most likely due to increased receptor number or enhanced coupling of the receptor to intracellular signaling processes. This phenomenon usually occurs with chronic reduction in receptor stimulation due to diminished endogenous agonists (e.g., after autonomic or motor nerve destruction). Reversal of prolonged antagonist therapy has also been associated with receptor supersensitivity (e.g., abrupt withdrawal of  $\beta$ -blocker therapy).

**IV. PHARMACODYNAMICS IN THE CLINICAL POPULATION.** Pharmacological therapy in the human patient population is fundamentally based on the principles of dose–response relationships, with higher doses producing greater effects until a maximum is reached. An inherent assumption of the dose dependency of a drug effect is that it is mediated through a specific receptor, regardless of whether the drug is an agonist or antagonist. However, the relative potencies of drugs (as indicated by the  $ED_{50}$ s) may not reflect the affinity of the drug for its receptor because this value can also be influenced by several pharmacokinetic parameters; that is, a high-affinity drug may exhibit a greater  $ED_{50}$  than a low-affinity drug if the former is poorly absorbed or more quickly inactivated by hepatic systems.

- A. Quantal dose–response relationship** may be developed in a patient population based on the dose required to produce a specific outcome; for example, the dose required to cause sleep or produce a 10% decrease in blood pressure. This would result in some individuals requiring very small doses, whereas others would need much higher amounts to induce the effect, the overall response following a Gaussian or normal distribution (Figure 58-8A). The mean of this distribution would be equivalent to the  $ED_{50}$  and 95% of patients would respond to a dose that is 2 standard deviations above or below the  $ED_{50}$  (indicated by the range shown in Figure 58-8A). Plotting the same data as the administered dose versus the cumulative number of patients producing the effect exhibits the recognizable dose–response curve (Figure 58-8B).
- B. Graded dose–response relationship** may be seen in a patient population or individuals where increasing doses of a drug results in greater pharmacological effect. This is best demonstrated by drugs that can be titrated to produce a desired outcome; for example, 10, 20, 40, and 80 mg of atorvastatin (Lipitor®) can produce 33%, 38%, 45%, and 53% lowering in LDL cholesterol, respectively (see Figure 10-17).
- C. Dose-dependent drug toxicity** can also result in the course of pharmacological therapy and follows a similar normal distribution as demonstrated in Figure 58-8A—only these effects usually occur at higher doses (e.g., 1% of the population may show toxicity to the same drug at 6 mg/kg). Plotting graded dose–response curves for the therapeutic and toxic effects of drug may produce relationships as seen in Figure 58-9. From the graph, it can be seen that the dose-producing toxicity in 50% of the population ( $TD_{50}$ ) is larger than the  $ED_{50}$ ; however, the  $TD_{1}$  is much closer to the  $ED_{99}$  and is an indication of the margin of safety of the drug. If the toxic effect being measured is death, then the lethal dose producing 50% death in the population is called the  $LD_{50}$ , and the ratio of the  $LD_{50}$  to the  $ED_{50}$  is called the therapeutic index. Drugs with a low margin of safety are likely to show toxicity at doses that are in the therapeutic range (e.g., warfarin [Coumadin®] and digoxin [Lanoxin®]).

**Figure 58-8.** A. The percentage of patients in a population that respond to a pharmacological intervention can be represented by a Gaussian distribution where some require only 1 mg and others need as much as 5 mg of the drug to show the desired response. This in effect is the dose–response relationship of the entire population as demonstrated by the graph (B) where plotting the cumulative number of responders after each dose gives the classic dose–response curve. In either graph, the dose producing an effect in 50% of the population ( $ED_{50}$ ) can be determined as shown.

**Figure 58-9.** Drugs can have toxic or undesirable effects that follow a dose–response relationship; however, these effects often require higher doses to be observed and thus their graph appears shifted to the right of the therapeutic effect (*graph on the right*). TD<sub>1</sub>: dose producing a toxic response in 1% of the population.

## V. STRUCTURAL DETERMINANTS OF DRUG ACTION

- A. **Structural specificity** is conferred by physical and chemical characteristics, or physicochemical properties, of drugs that allow for specific binding and modulation of the target receptor. These physicochemical properties of a drug are influenced by the acid–base character, water solubility, and stereochemistry, which are dependent on the chemical structure. The physicochemical properties are also important for absorption, distribution, metabolism, and excretion. This structure–function connection is the basis for **structure–activity relationships** (SARs) that are defined by changing the chemical structure and determining its influence on biological activity.
- B. **Pharmacophore** is a term used to describe the critical organic functional groups and their spatial relationship within a drug molecule required for a specific pharmacological activity. Drugs with similar structure and the same pharmacophore typically have similar pharmacological activity but may have other ADME characteristics or potencies that distinguish them from one another.
- C. A **functional group** is a specific group of atoms that have a distinctive acid–base character, contribution to water solubility, and chemical reactivity. The combination of multiple functional groups can influence the properties of adjacent functional groups and together define the physicochemical properties of the drug molecule. Common functional groups are shown in *Tables 58-1, 58-2, and 58-3*.
- D. A **bioisostere** is a compound containing an atom or group of atoms that is spatially and electronically similar to another molecule that produces a similar biological activity. The goal of bioisosteric replacement is frequently to increase potency, decrease side effects, separate biological activities, or increase the duration of action by altering metabolism. Additionally, bioisosteric substitutions may result in a compound that is an antagonist or inhibitor of the parent molecule; for example, allopurinol (Zyloprim®) inhibits xanthine oxidase, which, through a multistep metabolic process, converts hypoxanthine to uric acid (*Figure 58-10*).
- E. The **stereochemistry** of a drug molecule also contributes to the structural specificity of a drug by defining the three-dimensional spatial arrangement of the functional groups required for receptor interactions. **Stereoisomers** have the same atoms and connectivity but different arrangements in space. Stereoisomers can be divided into three main groups: enantiomers; diastereomers, including geometric isomers; and conformational isomers.
  1. **Enantiomers** are nonsuperimposable mirror images of each other because they contain at least one asymmetric, or chiral, center, usually a carbon covalently bound to four different substituents. A drug containing one chiral carbon can exist in one of two nonsuperimposable isomeric forms, although a drug with multiple chiral centers ( $n$ ) has the potential to exist in one of  $2^n$  isomeric forms that are enantiomers or diastereomers (*Figure 58-11*).
    - a. Enantiomers have identical physical and chemical properties except for the direction of rotation of plane-polarized light measured in a polarimeter. One isomer will rotate plane-polarized light in a clockwise direction (**dextrorotatory**;  $d$  or  $+$ ) and the other in a counterclockwise direction (**levorotatory**;  $l$  or  $-$ ).
    - b. An equal molar mixture of a pair of enantiomers ( $+$  and  $-$ ) is called a **racemic mixture** or **racemate**. A racemate has a net zero rotation of plane-polarized light and is therefore optically inactive. Currently, some active drugs are marketed both as a racemate (cetirizine [Zyrtec®]) and as an enantiomerically pure product (levocetirizine [Xyzal®]) (*Figure 58-11*).

**Table 58-1** NEUTRAL FUNCTIONAL GROUPS

Group	Structure	Group	Structure
Alkane	$\text{H}_3\text{C}-\text{CH}_2-\text{CH}_2-\text{CH}_3$	Ketone	$\text{H}_3\text{C}-\overset{\text{O}}{\parallel}{\text{C}}-\text{CH}_3$
Alkene	$\begin{array}{c} \text{H} \quad \text{CH}_3 \\ \diagdown \quad / \\ \text{C}=\text{C} \\ / \quad \diagdown \\ \text{H}_3\text{C} \quad \text{H} \end{array}$	Amine (quaternary)	$\begin{array}{c} \text{H}_3\text{CH}_2\text{C} \quad \text{CH}_2\text{CH}_3 \\ \diagdown \quad / \\ \text{N}^+ \\ / \quad \diagdown \\ \text{H}_3\text{CH}_2\text{C} \quad \text{CH}_2\text{CH}_3 \end{array}$
Aromatic		Ester	$\text{H}_3\text{CH}_2\text{C}-\overset{\text{O}}{\parallel}{\text{C}}-\text{OCH}_2\text{CH}_3$ or $\text{CH}_3\text{CH}_2\text{COOCH}_2\text{CH}_3$
Alcohol (primary)	$\text{H}_3\text{C}-\text{OH}$	Amide	$\text{H}_3\text{CH}_2\text{C}-\overset{\text{O}}{\parallel}{\text{C}}-\text{NHCH}_2\text{CH}_3$
Alcohol (secondary)	$\begin{array}{c} \text{H} \\   \\ \text{H}_3\text{C}-\text{C}-\text{OH} \\   \\ \text{CH}_3 \end{array}$	Carbonate	$\text{H}_3\text{CH}_2\text{CO}-\overset{\text{O}}{\parallel}{\text{C}}-\text{OCH}_2\text{CH}_3$
Alcohol (tertiary)	$\begin{array}{c} \text{CH}_3 \\   \\ \text{H}_3\text{C}-\text{C}-\text{OH} \\   \\ \text{CH}_3 \end{array}$	Carbamate	$\text{H}_3\text{CH}_2\text{CO}-\overset{\text{O}}{\parallel}{\text{C}}-\text{NHCH}_2\text{CH}_3$
Ether	$\text{H}_3\text{CH}_2\text{C}-\text{O}-\text{CH}_2\text{CH}_3$	Urea	$\text{H}_3\text{CH}_2\text{CHN}-\overset{\text{O}}{\parallel}{\text{C}}-\text{NHCH}_2\text{CH}_3$
Thioether	$\text{H}_3\text{CH}_2\text{C}-\text{S}-\text{CH}_2\text{CH}_3$	Nitro	$\begin{array}{c} \ominus \\   \\ \text{H}_3\text{CH}_2\text{C}-\text{N}^+ \\ // \quad   \\ \text{O} \quad \text{O} \end{array}$ or $\text{H}_3\text{CH}_2\text{C}-\text{NO}_2$
Aldehyde	$\text{H}_3\text{C}-\overset{\text{O}}{\parallel}{\text{C}}-\text{H}$	Nitrate	$\text{H}_3\text{CH}_2\text{C}-\text{O}-\text{NO}_2$

- c. Enantiomers can have large differences in potency, receptor fit, biological activity, transport, and metabolism. These differences result when the drug molecule has an asymmetric interaction with a receptor, a transport protein, or a metabolizing enzyme. The enantiomer with the desired pharmacological effect is called the **eutomer**, whereas the other isomer is the **distomer**. The distomer may not have pharmacologic activity or may be responsible for adverse effects.
- d. Enantiomers are distinguishable in a chiral environment, including the human body, or by determining the rotation of plane-polarized light in a polarimeter. These are properties of the molecule but they do not reveal information concerning the absolute configuration around the chiral center. To determine the absolute configuration, the Cahn-Ingold-Prelog (CIP) system for assigning priority is used (R or S designation). It is important to remember that the CIP absolute configuration is applied to each chiral center and is independent of the direction of rotation of plane-polarized light for the molecule as a whole. In a pair of enantiomers, all stereocenters are opposite in their absolute configuration and therefore also in their CIP designation.
2. **Diastereomers** are stereoisomers that are not enantiomers. More specifically, they are stereoisomers that are not mirror images of each other or superimposable.
- a. Like enantiomers, diastereomers can be optically active. But diastereomers have some stereocenters that are identical and some that are opposite in their absolute configuration. Diastereomers

## BASIC FUNCTIONAL GROUPS

Group	Structure
Amine (primary)	$\text{H}_3\text{CH}_2\text{C}-\text{NH}_2$
Amine (secondary)	$\text{H}_3\text{CH}_2\text{C}-\text{NH}-\text{CH}_2\text{CH}_3$
Amine (tertiary)	$\text{H}_3\text{CH}_2\text{C}-\text{N}(\text{CH}_2\text{CH}_3)_2$
Amine (aromatic)	
Imine	$\text{H}_3\text{C}=\text{NH}$
Amidine	$\text{H}_3\text{CH}_2\text{C}-\overset{\text{NH}}{\parallel}{\text{C}}-\text{NH}_2$
Guanidine	$\text{H}_3\text{CH}_2\text{C}-\text{N}(\text{H})-\overset{\text{NH}_2}{\parallel}{\text{C}}-\text{NH}_2$

**Figure 58-10.** Bioisosteric pairs procainamide/procaine and allopurinol/hypoxanthine. The isosteric replacements are boxed.

possess different physicochemical properties and thus differ in properties such as solubility, volatility, and melting point. For optically active diastereomers, two or more stereocenters are required.

- b. Epimers** are a special type of diastereomers because epimers are structurally identical in all respect except for the stereochemistry of one chiral center. The process of **epimerization** (in which the stereochemistry of one chiral center is inverted) is important in drug degradation and inactivation (*Figure 58-12*).
  - c. Geometric isomers** are diastereomers because they are not mirror images and they have different physicochemical properties and pharmacologic activity (*Figure 58-13*). Geometric isomers are also called **cis-trans isomers** and result from restricted rotation around a chemical bond. This can be an alkene (double bond) or a fused ring system within a molecule that prevents interconversion between the two isomers.
3. Conformational isomers, also known as rotamers or conformers, are nonsuperimposable orientations of a molecule that results from the free rotation of atoms around a single bond. Almost every drug can exist in more than one conformation, and this ability allows many drugs to bind to multiple receptors and receptor subtypes. For example, the trans conformation of acetylcholine binds to the muscarinic receptor, whereas the gauche conformation of acetylcholine binds to the nicotinic receptor (*Figure 58-14*). It should be noted that conformational isomers are chemically indistinguishable (i.e., they have all the same physicochemical properties) from each other because the only difference between the conformers is the free rotation around a bond.

**Figure 58-11.** The two enantiomers of cetirizine. The chiral, or asymmetric, carbon is bonded to four different groups: a piperazine ring, a chlorinated benzene ring, an unsubstituted benzene, and a hydrogen. The structures shown are mirror images, which cannot be superimposed. A racemic mixture of cetirizine is marketed as Zyrtec, whereas the enantiomerically pure levocetirizine is marketed as Xyzal.

**Figure 58-12.** Epimerization of tetracycline to 4-epitetracycline. The stereochemistry of the 4-dimethylamino group is inverted; however, the stereochemistry of all other chiral centers remains unchanged.

**VI. PHYSIOCHEMICAL DETERMINANTS OF DRUG ACTION.** The polarity and acid–base property of a drug are two primary physiochemical characteristics of drugs.

**A. Polarity of drugs** is a measure of their lipid and water solubility and is generally expressed as the partition coefficient.

**1. Partition coefficient ( $P$ )** of a drug is the ratio of the solubility of the agent in an organic lipophilic solvent (usually *n*-octanol) to its solubility in water or aqueous buffer.

$$P = \frac{[\text{Drug}]_{\text{organic}}}{[\text{Drug}]_{\text{water}}}$$

The partition coefficient is often expressed as the logarithmic value,  $\log P$ .

**2. Water solubility** or hydrophilicity of a drug is dependent on two major factors: its ionic and hydrogen-bonding capacity. The presence of oxygen- and nitrogen-containing functional groups generally enhances water solubility, which is required for

- a. drug dissolution in the gastrointestinal (GI) tract,
- b. preparation of parenteral drug solutions, and
- c. ophthalmic drug solutions.

**3. Lipid solubility** or lipophilicity is increased by the presence of nonionizable functional groups (hydrocarbon chains or ring systems) and is important in

- a. drug absorption from the GI tract,
- b. penetration of drug through biological membranes (e.g., cell membranes, blood–brain barrier),
- c. preparation of intramuscular depot injectable formulations,
- d. drug absorption via the pulmonary route,
- e. increased potency of topically applied formulations, and
- f. increased plasma protein binding.

**Figure 58-13.** The presence of the double bond in diethylstilbestrol allows for the formation of *cis* and *trans* geometric isomers. The functional groups of these isomers are separated by different distances; they generally do not fit the same receptor equally well. As a result, the *trans* isomer has estrogenic activity and the *cis* isomer only has 7% the estrogenic activity of the *trans* isomer.

**Figure 58-14.** The *trans* (A) and *gauche* (B) conformations of acetylcholine occur as the result of rotation around the carbon-carbon single bond.

**B. Acid-base characteristic** of drugs influence their ionization in biological fluids. Using the Brønsted-Lowry definition, acids donate a proton to become ionized, whereas bases accept a proton to become ionized.

- The **ionization constant ( $K_a$ )** indicates the relative strength of the acid or base by indicating the ratio of the unprotonated species to the protonated species (Figure 58-15). An acid with a  $K_a$  of  $1 \times 10^{-3}$  is stronger (more ionized [ $A^-$ ] species) than an acid with a  $K_a$  of  $1 \times 10^{-5}$ , whereas a base with a  $K_a$  of  $1 \times 10^{-7}$  is weaker (less ionized [ $BH^+$ ] species) than a base with a  $K_a$  of  $1 \times 10^{-9}$ .
- The ionization constant is more commonly reported as the  **$pK_a$**  or the **negative log of the ionization constant**. The  $pK_a$  also indicates the relative strength of the acid or base. Using the aforementioned examples, an acid with a  $K_a$  of  $1 \times 10^{-3}$  has a  $pK_a$  of 3 and is stronger than an acid with a  $K_a$  of  $1 \times 10^{-5}$  ( $pK_a$  of 5), whereas a base with a  $K_a$  of  $1 \times 10^{-7}$  ( $pK_a$  of 7) is weaker than a base with a  $K_a$  of  $1 \times 10^{-9}$  ( $pK_a$  of 9).
- Acids** can be described as strong or weak acids based on their ability to donate a proton.
  - Strong acids** are completely ionized when placed in water. Strong acids include hydrochloric acid (HCl), sulfuric acid ( $H_2SO_4$ ), nitric acid ( $HNO_3$ ), hydrobromic acid (HBr), iodic acid ( $HIO_3$ ), and perchloric acid ( $HClO_4$ ).
  - Weak acids** are partially ionized when placed in water. Most organic acids contained in drugs are weak acids. The following functional groups are weak acids. The approximate  $pK_a$  range is shown in parentheses (see Table 58.2).
    - Carboxylic acid group ( $-COOH$  with a  $pK_a$  range of 4–6)
    - Phenolic group ( $Ar-OH$  with a  $pK_a$  range of 9–11)
    - Sulfonic acid group ( $-SO_3H$  with a  $pK_a$  range of 0–1)
    - Sulfonamide group ( $-SO_2NH_2$  with a  $pK_a$  range of 9–10)
    - N-Aryl sulfonamide group ( $-SO_2NH-Ar$  with a  $pK_a$  range of 6–7)
    - Imide group ( $-CO-NH-CO-$  with a  $pK_a$  range of 9–10)
    - Thiol ( $R-SH$  with a  $pK_a$  range of 9–11)
    - Sulfonimide ( $-SO_2NH-CO-$  with a  $pK_a$  range of 5–6)
    - Tetrazole (five-member ring  $CHN_4$  with a  $pK_a$  range of 4–6)
  - When a weak acid, like acetic acid ( $pK_a = 4.76$ ), is placed in an acid medium (high  $[H^+]$ , low pH), the equilibrium shifts to the left and suppresses ionization. This decrease in ionization conforms to Le Chatelier's principle, which states that when a stress is placed on an equilibrium reaction, the

$$K_a = \frac{[H^+][A^-]}{[AH]} \quad \text{or} \quad K_a = \frac{[H^+][B:]}{[BH^+]}$$

$$pK_a = -\log K_a = \log \frac{1}{K_a}$$

**Figure 58-15.** The ionization constant ( $K_a$ ) and the  $pK_a$  indicate the equilibrium between the protonated species, the unprotonated species, and the strength of the acid or base.

reaction will move in the direction that tends to relieve the stress. When the same weak acid is placed in an alkaline medium (very low  $[H^+]$ , high pH), the ionization increases producing more  $H^+$ .

- d. Weakly acidic drugs are less ionized in acid media than in alkaline media. When the  $pK_a$  of an acidic drug is greater than the pH of the medium in which it exists, it will be  $> 50\%$  in its nonionized form and thus more likely to cross lipid cellular membranes.
4. **Bases** can be described as strong or weak bases based on their ability to accept a proton.
- a. **Strong bases** are completely ionized when placed in water. Strong bases include sodium hydroxide (NaOH), potassium hydroxide (KOH), magnesium hydroxide ( $Mg(OH)_2$ ), calcium hydroxide ( $Ca(OH)_2$ ), barium hydroxide ( $Ba(OH)_2$ ), and quaternary ammonium hydroxides.
- b. **Weak bases** are partially ionized when placed in water. Most organic bases contained in drugs are weak bases. The following functional groups are weak bases. The approximate  $pK_a$  range is shown in parentheses (see *Table 58.3*).
- (1) Primary, secondary, and tertiary aliphatic amines ( $R-NH_2$ ,  $R_2-NH$ , and  $R_3-N$ , respectively, with a  $pK_a$  range of 9–11)
  - (2) Aromatic amine (aromatic ring with N included in ring with a  $pK_a$  range of 5–6)
  - (3) Arylamine ( $Ar-NH_2$  with a  $pK_a$  range of 4–5)
  - (4) Imine ( $-CH=NH$  with a  $pK_a$  range of 3–4)
  - (5) Amidine ( $-NH-C=N-$  with a  $pK_a$  range of 10–11)
  - (6) Guanidine ( $-NH-C=NH(NH_2)$  with a  $pK_a$  range of 12–13)
- c. When a weak base like ethylamine ( $pK_a = 10.7$ ) is placed in an acid medium (high  $[H^+]$ , low pH), the equilibrium shifts to the left and increases the ionization (see Le Chatelier's principle in section VI.B.3.c). When the same weak base is placed in an alkaline medium (very low  $[H^+]$ , high pH), the ionization decreases.

- d. Weakly basic drugs are less ionized in alkaline media than in acid media. When the  $pK_a$  of a basic drug is less than the pH of the medium in which it exists, it will be  $> 50\%$  in its nonionized form and thus more likely to cross lipid cellular membranes.
5. **Percent ionization** can be approximated by using the rule of nines. If the  $|pH - pK_a| = 1$ , then a 90:10 ratio (one nine in the ratio) exists. If the  $|pH - pK_a| = 2$ , the ratio becomes 99:1 (two nines in the ratio), and if the  $|pH - pK_a| = 3$ , the ratio becomes 99.9:0.1 (three nines in the ratio). The predominant form, ionized or unionized, in these ratios can be easily determined.
6. **Drug salts** are made by the combination of an acid and a base. Because most drugs are organic molecules, drug salts can be divided into two classes based on the chemical nature of the substance forming the salt.
- a. **Inorganic salts** are made by combining drug molecules (a weak base or acid) with strong inorganic acids or bases such as hydrochloric acid, sulfuric acid, potassium hydroxide, or sodium hydroxide. The salt form of the drug made from a strong inorganic and a weak organic generally has increased water solubility in comparison with the parent molecule and increased aqueous dissolution.
- b. **Organic salts** are made by combining drug molecules with either small hydrophilic organic compounds (e.g., succinic acid, citric acid) or lipophilic organic compounds (e.g., procaine). Water-soluble organic salts are used to increase dissolution and bioavailability as well as to aid in the preparation of parenteral and ophthalmic formulations. Lipid-soluble organic salts are primarily used to make depot injections.
- c. **Dissolution of salts** can alter the pH of an aqueous medium.
- (1) Salts of strong acids (e.g., HCl,  $H_2SO_4$ ) and basic drugs dissociate in an aqueous medium to yield an acidic solution.
  - (2) Salts of strong bases (e.g., NaOH, KOH) and acidic drugs dissociate in an aqueous medium to yield a basic solution.
  - (3) Salts of weak acids and weak bases dissociate in an aqueous medium to yield an acidic, basic, or neutral solution, depending on the respective ionization constants involved.

- (4) Salts of strong acids and strong bases (e.g., NaCl) do not significantly alter the pH of an aqueous medium.
7. **Amphoteric drugs** contain both acidic and basic functional groups and are capable of forming internal salts, or zwitterions, which often have dissolution problems because the ions interact with each other and not the aqueous environment.
  8. A **neutralization reaction** might occur when an acidic solution of an organic salt (a solution of a salt of a strong acid and a weak base) is mixed with a basic solution (a solution of a salt of a weak acid and a strong base). The nonionized organic acid or the nonionized organic base is likely to precipitate in this case. The reaction is the basis for many drug incompatibilities, particularly when intravenous solutions are mixed.

**VII. NONCLASSICAL ACTIONS OF DRUGS.** Some pharmacological agents appear to produce their therapeutic effects without interacting with a specific receptor protein, in a manner described by canonical drug–receptor characteristics. The following list is not exhaustive and may change as research explains previous “nonspecific” mechanisms; for example, inhalational anesthetics (e.g., halothane) have been shown to have specific interactions with and modulation of GABA<sub>A</sub> receptors.

**A. Interaction with membranes**

1. **Polyene antifungal agents** (e.g., amphotericin B [Ambisome®]) interact with fungal membrane sterols to cause pore formation and cell lysis.
2. **Alcohols, solvents** (e.g., ethanol, isopropyl alcohol, phenol, chlorhexidine) dissolve bacterial membranes to produce cell lysis.
3. **Certain antibiotics** (e.g., polymyxin B) interact with phospholipid components of bacterial membranes to cause cell lysis.

**B. Interaction with cytoskeletal components.** Microtubule disruptors (e.g., vincristine [Vincasar®], paclitaxel [Taxol®]) interact with tubulin filaments to interfere with their role in mediating cell division.

**C. Interaction with DNA/RNA**

1. **Alkylating agents** (e.g., nitrosoureas, nitrogen mustards) react with components such as the pyrimidine and purine bases causing cross-linking of DNA strands.
2. **DNA-intercalating agents** (e.g., actinomycin D [Dactinomycin®]) interact with adjacent G-C bases and the minor groove of the DNA double helix.
3. **DNA-cleaving agents** (e.g., bleomycin [Blenoxane®]) bind to DNA causing localized oxidative stress and DNA strand breaks.

**D. Neutralizing reactions**

1. **Acid–base interactions** (e.g., aluminum sulfate, calcium carbonate) react with peptic HCl to reduce symptoms of dyspepsia. The inactivation of heparin by protamine sulfate is another example of this type of neutralization.
2. **Chelators** (e.g., EDTA, dimercaprol) bind metal ions such as Ca<sup>2+</sup>, Pb<sup>2+</sup>, and Hg<sup>2+</sup> with high affinity and enhance their removal from the body.
3. **Antibody–antigen complexes** (e.g., antivenoms, antidigoxin antibodies [Digibind®]) are administered to rapidly decrease systemic toxins or drugs via the immune system.

**VIII. MAJOR SOURCES OF COMMERCIALY VIABLE DRUGS**

**A. Naturally occurring** drugs are usually obtained from plant or animal sources.

1. **Alkaloids** are nitrogen-containing compounds occurring in plants and possessing pharmacological activity. Most alkaloids have a basic character (e.g., morphine from opium poppy or atropine from belladonna), whereas others are neutral amides (e.g., colchicines from autumn crocus). All alkaloids end in the suffix *-ine*; however, not all drugs that end with this suffix are alkaloids (e.g., nifedipine [Procardia®] or meperidine [Demerol®]).
2. **Hormones** are endogenous chemicals released into the blood by a tissue or organ to act on more distant tissues or organs. These may be biogenic amines, peptides/proteins, or steroids.
  - a. **Biogenic amines** such as epinephrine are released by the adrenal medulla to alter the function of multiple organ systems during sympathetic activation.
  - b. **Steroids** such as testosterone, estradiol, cortisol, etc. are chemical derivatives of cyclopentanoperhydrophenanthrene and often obtained from animal or human sources.

- c. **Peptides/proteins** such as insulin, glucagon, and somatostatin are obtained from animal sources or recombinant DNA technology. Generally, peptide and protein drugs have limited oral activity and have to be administered parenterally.
  3. **Glycosides** are drugs that contain a sugar moiety bound to a nonsugar or aglycone portion via glycosidic bonds and are most often from plant (e.g., digoxin) or microbial (e.g., streptomycin, doxorubicin) sources.
  4. **Polysaccharides** are drugs composed of sugar polymers from human or animal sources (e.g., heparin, enoxaparin). Structural modification of naturally occurring sugars can yield additional drugs (e.g., sucralfate [Carafate<sup>®</sup>]).
  5. **Antibiotics** are often fungal or other microbial products that have suppressive or lethal effects on other microorganisms (e.g., penicillin, tetracycline).
  6. **Vitamins** are plant and animal products that function as essential cofactors for various metabolic processes in the body. Water-soluble vitamins include thiamine (B1), riboflavin (B2), niacin (B3), pyridoxine (B6), cyanocobalamin (B12), ascorbic acid (C), folic acid, pantothenic acid, and biotin (H). Fat-soluble vitamins include  $\alpha$ -tocopherol (E), ergocalciferol (D), retinol (A), and phytonadione (K).
- B. Synthetic products**
1. **Small organic molecules** produced by organic synthesis to mimic the activity of naturally occurring chemicals or found to have unique pharmacological activity not previously identified.
    - a. **Antimicrobials** (e.g., ciprofloxacin [Cipro<sup>®</sup>] or trimethoprim) are man-made chemicals that inhibit unique microbial targets such as the DNA gyrase or dihydrofolate reductase to treat susceptible infections.
    - b. **Receptor ligands** compose the largest group of drugs and often mimic endogenous receptor ligands; for example, propranolol (Inderal<sup>®</sup>) has structural homology to epinephrine; meperidine (Demerol) mimics the structural features of endorphins at the  $\mu$ -opiate receptors.
    - c. **Enzyme inhibitors** may be targeted against microbial proteins as in section VIII.B.1.a above or mammalian enzymes; for example, aliskiren (Tekturna<sup>®</sup>) against renin, pravastatin (Pravachol<sup>®</sup>) against hepatic HMG-CoA reductase, or imatinib (Gleevec<sup>®</sup>) against c-kit tyrosine kinase.
  2. **Peptides/proteins**
    - a. Peptides. Eptifibatid (Integrilin<sup>®</sup>) is a synthetic cyclic peptide that mimics components of carpet viper venom to prevent platelet aggregation.
    - b. Proteins. Lepirudin (Refludan<sup>®</sup>) is a recombinant, synthetic derivative of hirudin, the anticoagulant from leeches.
  3. **Polysaccharides.** The synthetic pentasaccharide fondaparinux (Arixtra<sup>®</sup>) mimics the portions of heparins that interact with coagulant proteins.

## Study Questions

**Directions:** Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. All of the following are examples of specific receptors for drug action **except**
  - (A) stomach acid.
  - (B) membrane proteins.
  - (C) cytoplasmic proteins.
  - (D) nuclear proteins.
  - (E) DNA.
2. A 40-year-old teacher was prescribed lovastatin for the treatment of hypercholesterolemia. She wanted to know the mechanism of the drug before taking it. Her pharmacist explained to her that lovastatin acts by blocking the substrate-binding site of the enzyme  $\beta$ -hydroxy- $\beta$ -methylglutaryl-coenzyme A (HMG-CoA) reductase, which catalyzes the rate-limiting step in cholesterol biosynthesis. Such drug effect is known as
  - (A) addition.
  - (B) synergism.
  - (C) noncompetitive antagonism.
  - (D) potentiation.
  - (E) competitive antagonism.

3. A 70-year-old man had prolonged bleeding during an elective knee surgery. Subsequently, the patient admitted to the surgeon that he had been self-administering 81 mg aspirin daily. The consultant pharmacist explained to the patient that, although aspirin has a short plasma half-life, it can irreversibly inhibit platelet function by acetylating the nonsubstrate-binding site of the platelet cyclooxygenase, resulting in prolonged effect on platelet aggregation. This drug effect is known as
- potentiation.
  - competitive antagonism.
  - synergism.
  - addition.
  - noncompetitive antagonism.
4. A 65-year-old woman with intractable pain secondary to bony metastasis of breast cancer had been receiving escalating doses of morphine sulfate intravenously. At 10 A.M., she was found to be unresponsive, her respiratory rate was 4 breaths per minute, and her pupils were pinpointed. Naloxone (Narcan), a competitive antagonist of the opiate receptor, was given intravenously and repeated once. She gradually became conscious and began to complain of pain unrelieved by morphine given at the previous dose. This is most likely because
- naloxone directly aggravates the pain caused by the bony metastasis.
  - naloxone reduces the  $E_{max}$  for morphine.
  - naloxone reduces the  $ED_{50}$  for morphine.
  - naloxone increases the  $E_{max}$  for morphine.
  - naloxone increases the  $ED_{50}$  for morphine.
5. Which of the following statements regarding signal transduction is **incorrect**?
- Thyroxine-bound receptors act on DNA and regulate specific transcription of genes.
  - Cyclic adenosine monophosphate can act as a second messenger.
  - The level of drug receptors at the cell surface increases with chronic stimulation by receptor agonists.
  - Binding of ligand to cell surface receptors can lead to synthesis of proteins.
  - Antacids act by interacting with small ions normally found in the gastrointestinal tract.
6. A pharmacist is consulted about selecting a drug that is relatively safe and effective for treating the patient. He searches the literature and obtains the following data that may help guide his decision. The  $TD_{0.1}$  and  $ED_{99.9}$  for drug A are 20 mg and 0.4 mg, respectively; whereas the  $TD_{0.1}$  and  $ED_{99.9}$  for drug B are 15 mg and 0.2 mg, respectively. Which of the following statements is true?
- Drug A has a higher  $TD_{0.1}$  and thus should be the drug of choice.
  - Both drugs have the same margin of safety, so more information is needed.
  - Drug B has a higher margin of safety and thus is preferred to drug A.
  - Drug A is preferred because it has a greater margin of safety than drug B.
  - The information obtained is irrelevant.
7. Which of the following statements concerning a drug receptor is true?
- It is only found on the plasma membranes of cells.
  - Its expression is induced only by exogenously added drugs.
  - It can bind endogenous ligand to produce physiological activity.
  - It is mostly composed of sugars (polysaccharides).
  - Receptor desensitization or downregulation have no impact on the therapeutic effect of the drug.
8. Which of the following statements concerning morphine and hydromorphone (Dilaudid) is true?
- Hydromorphone is a more effective analgesic because it has a smaller  $ED_{50}$  than morphine.
  - Morphine and hydromorphone are equally potent because they have the same  $E_{max}$ .
  - Morphine has a greater  $ED_{50}$  and is thus a less effective analgesic than hydromorphone.
  - Hydromorphone is a more potent analgesic because it has a greater  $E_{max}$  than morphine.
  - Hydromorphone has a smaller  $ED_{50}$  and thus is a more potent analgesic than morphine.

9. A 72-year-old man with hypertension has been taking high-dose propranolol (Inderal) for 20 years. He left home for a week and forgot to bring his medication with him. One day, he was found collapsed on the floor and was brought to the emergency room. His blood pressure was 300/180, heart rate was 180 beats per minute, and retinal hemorrhage was observed. Which of the following best explains this situation?
- (A) The  $\beta$ -adrenergic receptors in the cardiac muscles underwent spontaneous mutation and became hyperactive.
  - (B) Reduction in the chronic antagonism of the  $\beta$ -adrenergic receptor led to downregulation of the  $\beta$ -adrenergic receptor.
  - (C) The propranolol that he had previously ingested remained in his body and acted as a receptor agonist.
  - (D) Long-term administration of propranolol results in desensitization of cardiac muscles to endogenous  $\beta$ -adrenergic stimulation.
  - (E) Reduction in the chronic level of receptor blockade results in supersensitivity to stimulation with endogenous catecholamines.
10. A 42-year-old man with non-small cell lung carcinoma tells his pharmacist that his doctor had prescribed erlotinib (Tarceva) for treating his cancer. The patient asked what erlotinib is and how it works. His pharmacist explains to him that it is a drug that
- (A) prevents the binding of growth factors to their receptors.
  - (B) prevents growth factors from activating their receptors.
  - (C) boosts the functions of growth factor receptors.
  - (D) neutralizes a receptor on cancer cells by an antibody mechanism.
11. A 65-year-old woman experienced anginal pain with ST-segment elevation on electrocardiogram (ECG). She was treated with IV heparin, nitroglycerin, and atenolol (Tenormin) for acute myocardial infarction. Then 2 hrs later, when her nurse replaced her Foley bag, she noticed frank blood draining out of the Foley catheter. The physician checked the patient's partial thrombin time, which was  $> 150$  secs. The patient was then administered protamine, which acts by
- (A) promoting thrombosis.
  - (B) reacting with and neutralizing the effect of heparin.
  - (C) directly inhibiting bleeding.
  - (D) enhancing secretion of procoagulants.
12. Inverse agonist is a relatively new designation for drug action that a physician asks you about. Your explanation would include the fact that
- (A) these agents may have biological function by altering the interaction between the receptor and G protein.
  - (B) there is no known drug with this type of effect.
  - (C) these agents can desensitize receptors to agonist stimulation.
  - (D) the inverse form of these drugs can stimulate physiological response.
13. A 55-year-old man with a history of heart disease was being treated with 20 mg of atorvastatin (Lipitor) but this was not adequate to bring his LDL cholesterol down to acceptable levels. So his physician increased the dose to 40 mg, which resulted in a 30% lowering in LDL. This would be an example of a
- (A) quantal dose–response relationship.
  - (B) population dose–response relationship.
  - (C) cumulative dose–response relationship.
  - (D) graded dose–response relationship.
14. All of the following are examples of non-receptor-mediated drug effects **except**
- (A) magnesium sulfate for treatment of constipation.
  - (B) calcium carbonate for relief of heartburn.
  - (C) halothane for inducing anesthesia.
  - (D) isopropyl alcohol used for its topical antibacterial activity.
  - (E) amphotericin B for fungal infections.
15. Which of the following salts will most likely yield an aqueous solution with a  $\text{pH} < 7$ ?
- (A) Sodium salicylate
  - (B) Potassium chloride
  - (C) Magnesium sulfate
  - (D) Potassium penicillin
  - (E) Atropine sulfate
16. All of the following functional groups are weak bases **except**
- (A) aromatic amines.
  - (B) sulfonamide.
  - (C) tertiary amines.
  - (D) imines.
17. The dissociation constant of a drug at its receptor is most closely related to
- (A) the maximal response produced by the drug.
  - (B) the number of spare receptors available.
  - (C) the affinity of the drug for the receptor.
  - (D) the total number of receptors available to the drug.
  - (E) allosterism.

18. All of the following statements about a structurally specific agonist are true **except**:
- Activity is determined more by its chemical structure than by its physical properties.
  - The entire molecule is involved in binding to a specific endogenous receptor.
  - The drug cannot act unless it is first bound to a receptor.
  - A minor structural change in a pharmacophore can produce a loss in activity.
  - The higher the affinity between the drug and its receptor, the greater the biological response.

19. The dextro (d) form of  $\beta$ -methacholine (structure shown) is approximately 500 times more active than the levo (l) enantiomer. The observed difference in pharmacological activity between the two isomers is most likely the result of differences in

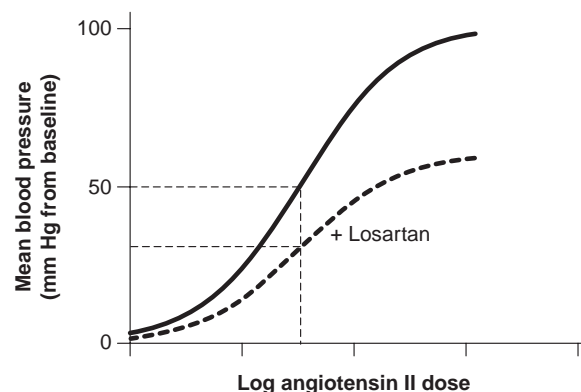

- receptor selectivity.
  - dissolution.
  - distribution.
  - interatomic distance between pharmacophore groups.
  - solubility.
20. The compound shown in the figure can be classified as a(n)

- acid.
  - base.
  - organic salt.
  - organic base.
  - inorganic salt.
21. Which of the following acids has the highest degree of ionization in an aqueous solution?
- Aspirin;  $pK_a = 3.5$
  - Indomethacin;  $pK_a = 4.5$
  - Warfarin;  $pK_a = 5.1$
  - Ibuprofen;  $pK_a = 5.2$
  - Phenobarbital;  $pK_a = 7.4$

22. The *solid line* on the graph in the following figure shows the change in mean blood pressure (from baseline of 90 mm Hg) with increasing bolus doses of angiotensin II in an experimental animal model. The *dashed line* is the response to the same doses of angiotensin II in the animal 2 hrs after an intravenous administration of 10 mg/kg of losartan, an antagonist of the angiotensin receptor. Based on the responses before and after the angiotensin antagonist, which of the following statements would most likely be true?

- Angiotensin II is a partial agonist.
  - Losartan may interact irreversibly with the angiotensin receptor.
  - Losartan is a partial agonist.
  - Angiotensin II may be an inverse agonist.
  - Angiotensin and losartan are probably working at different sites in the animal.
23. The structure–activity relationship of a drug can be altered by all of the following parameters **except**
- stereochemistry.
  - specific functional groups.
  - bioisosteric substitution.
  - cis-trans* conformation.
  - the salt form of the drug.
24. Flurazepam has  $pK_a$  of 8.2. What percentage of flurazepam will be ionized at a urine pH of 5.2?

- 0.1%
- 1%
- 50%
- 99%
- 99.9%

25. Which of the following isomers can only be distinguished in a chiral environment or by measuring the direction of rotation of plane-polarized light in a polarimeter?
- geometric isomers
  - enantiomers
  - diastereomers
  - bioisosteres
26. The organic functional groups responsible for a particular pharmacological activity are called a(n)
- bioisostere.
  - eutomer.
  - epimer.
  - pharmacophore.
  - stereochemistry.
27. All of the following are basic functional groups **except**
- guanidine.
  - primary amine.
  - amide.
  - amidine.
  - tertiary amine.
28. The partition coefficient (P) of a drug is best described as
- the water solubility of a drug at a specific pH.
  - the presence of nonionizable functional groups that make a drug lipid soluble.
  - the ratio of drug solubility in a lipophilic solvent to solubility in an aqueous solvent.
  - the presence of ionizable functional groups that make a drug water soluble.
  - the characterization of a drug as an acid or a base.
29. An inorganic salt of imide containing drug can be made by the addition of which of the following?
- NaOH
  - H<sub>2</sub>SO<sub>4</sub>
  - HCl
  - HNO<sub>3</sub>
  - HBr
30. Which of the following statements may be true of drugs that are enzyme inhibitors?
- They may be destroyed by the enzyme/receptor.
  - They can bind to a site different from that of the substrate.
  - They can form covalent bonds with their receptors.
31. Examples of strong electrolytes (i.e., completely dissociated in an aqueous solution) include
- acetic acid.
  - pentobarbital sodium.
  - diphenhydramine hydrochloride.
32. Precipitation may occur when mixing aqueous solutions of meperidine hydrochloride with which of the following solutions?
- Sodium bicarbonate injection
  - Atropine sulfate injection
  - Sodium chloride injection
33. Drugs classified as synthetic include which of the following?
- epinephrine
  - morphine
  - fondaparinux
34. The excretion of a weakly acidic drug is generally more rapid in alkaline urine than in acidic urine. This process occurs because
- a weak acid in alkaline media will exist primarily in its ionized form, which cannot be reabsorbed easily.
  - a weak acid in alkaline media will exist in its lipophilic form, which cannot be reabsorbed easily.
  - all drugs are excreted more rapidly in an alkaline urine.

**Questions 35–37:** Refer to the drug meperidine (Demerol; structure shown).

**Directions for questions 30–34:** The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, A–E.

- if **I only** is correct
- if **III only** is correct
- if **I and II** are correct
- if **II and III** are correct
- if **I, II, and III** are correct

35. Functional groups present in the molecule shown include
- an ester.
  - a tertiary amine.
  - a carboxylic acid.

36. Meperidine is classified as a

- I. weak acid.
- II. salt.
- III. weak base.

37. Assuming that meperidine is absorbed after oral administration and that a large percentage of the dose is excreted unchanged, the effect of alkalinization of the urine will increase its

- I. duration of action.
- II. rate of excretion.
- III. ionization in the glomerular filtrate.

38. Which of the following statements regarding digoxin (Lanoxin) would be true?

- I. It is a glycoside.
- II. It is a naturally occurring compound.
- III. It mimics the actions of an endogenous hormone.

**Directions for questions 39–43:** The relationship of each pair of structures shown in this section is most closely associated with **one** of the following terms. The terms may be used more than once or not at all.

Choose the **best** answer, A–E.

- (A) Geometric isomers
- (B) Enantiomers
- (C) Diastereomers
- (D) Bioisosteres
- (E) Conformational isomers

39.

40.

41.

42.

43.

## Answers and Explanations

**1. The answer is A** [see VII.D.1].

The receptor would be a specific entity of the cell that drugs interact with to modify cell behavior. Although stomach acid is neutralized by antacids, it is not considered a specific receptor.

**2. The answer is E** [see III.D.1].

Lovastatin reversibly binds to the substrate-binding site of the enzyme HMG-CoA reductase, which catalyzes the rate-limiting step in the synthesis of cholesterol, thus lowering the cholesterol level. Therefore, lovastatin inhibits the enzyme by competitive antagonism.

**3. The answer is E** [see III.D.2].

Aspirin can covalently modify the platelet cyclooxygenase through acetylation of the enzyme other than the substrate-binding site, causing irreversible inhibition of platelet aggregation. Therefore, aspirin inhibits platelet function by noncompetitive antagonism of cyclooxygenase.

**4. The answer is E** [see III.C.1].

Naloxone is a competitive antagonist of opiate receptor. If one compares the log dose–response curve of both morphine and naloxone to that of morphine alone, the morphine–naloxone curve is shifted to the right. As a result, the ED<sub>50</sub> for morphine is increased. This means that a larger than previous dose of morphine is required for achieving the same analgesic effect.

**5. The answer is C** [see III.E.2].

The level of drug receptors at the cell surface usually decreases when the target cells are chronically stimulated by receptor agonists. Downregulation of receptors may be a protective mechanism that can prevent the target cells from being overstimulated.

**6. The answer is C** [see IV.C].

The margin of safety of the two drugs can be helpful in guiding selection of a drug. Margin of safety is the ratio of TD<sub>0.1</sub> to ED<sub>99.9</sub>. Thus, the margin of safety for drug A is 20 mg ÷ 0.4 mg, or 50, whereas the margin of safety for drug B is 15 mg ÷ 0.2 mg, or 75. Because drug B has a greater margin of safety than drug A, drug B is relatively safe at the dosage given to produce the desired effect.

**7. The answer is C** [see II.A; III.C; III.E.1–2].

A drug receptor, such as muscarinic cholinergic receptor that can bind atropine, normally binds endogenous acetylcholine to produce the physiological responses controlled by the parasympathetic autonomic nervous system. Receptors may be found on plasma membranes, cytoplasm, or nuclei of cells and are primarily proteinaceous in nature, although they can have sugar or lipid modifications. Receptor downregulation may lead to the phenomenon of tachyphylaxis.

**8. The answer is E [see III.B.1].**

The efficacy of a drug is determined by its  $E_{\max}$ , whereas its potency is measured by the  $ED_{50}$ . Hydromorphone has a smaller  $ED_{50}$  and thus is a more potent analgesic than morphine. Hydromorphone and morphine are both agonists for opiate receptors, and they have the same analgesic efficacy (i.e., they have the same  $E_{\max}$ ) if sufficient amounts of both drugs are used.

**9. The answer is E [see III.E.3].**

A chronic level of blocking the  $\beta$ -adrenergic receptors by propranolol results in upregulation of the receptor level. When the patient ceased taking the drug, the cardiac muscles became supersensitive to stimulation with endogenous catecholamines. This resulted in the hypertensive crisis that caused cerebral hemorrhage and loss of consciousness.

**10. The answer is B [see III.C.4].**

Erlotinib is a small molecule that inhibits the tyrosine kinase domain of the epidermal growth factor (EGF) receptor on cancer cells.

**11. The answer is B [see VII.D.1].**

Protamine is a chemical antagonist of heparin that acts via an acid–base interaction.

**12. The answer is A [see III.C].**

Inverse agonists stabilize the form of the receptor that is not bound to G proteins and are not agonists in the classical sense. This uncoupling of receptor and G protein may reduce basal cellular signaling even in the absence of agonists.  $\beta$ -Receptor antagonists are thought to have this type of activity apart from preventing the actions of catecholamines.

**13. The answer is D [see IV.B].**

Increasing doses of a drug usually produces greater responses and this is described as a graded response. This would be true in an individual or a population of patients.

**14. The answer is C [see VII].**

All the choices have a nonreceptor mechanism for producing their effects except for halothane that activates inhibitory receptors on neurons.

**15. The answer is E [see VI.B.6].**

The solution must contain an acidic substance to have a  $pH < 7$ . Atropine sulfate is a salt of a weak base and a strong acid; therefore, its aqueous solution is acidic. Sodium salicylate and potassium penicillin are both salts of strong bases and weak acids; therefore, their aqueous solutions are alkaline. Magnesium sulfate and potassium chloride are salts of strong bases and strong acids; therefore, their aqueous solutions are neutral.

**16. The answer is B [see VI.B.3–4; Table 58-2; Table 58-3].**

All these groups would accept a proton under physiological conditions except the sulfonamide, which would donate a proton instead.

**17. The answer is C [see III.A].**

The dissociation constant of a drug is the concentration at which half the available receptors are bound and the inverse of this value is the affinity of the drug–receptor interaction.

**18. The answer is B [see V; VI].**

The binding of a drug to its receptor usually involves only specific functional groups. These groups make up what is known as the pharmacophore of the drug molecule. Although the entire drug molecule is present at the receptor site, only a portion of it, the pharmacophore, is required for a biological response. The affinity of drug–receptor interaction does not predict whether the drug behaves as an agonist (having biological activity) or an antagonist; in fact, antagonists often have higher affinities for the receptor than agonists.

**19. The answer is A [see V.E.1].**

The term *enantiomer* and the *d* and *l* indicate that the  $\beta$ -methacholine has a chiral center and exhibits optical isomerism. Because the optical isomers have different orientations in space, one orientation will give a better fit than the other and will most likely have greater biological activity than the other. Dissolution, distribution, interatomic distances, and solubility are all related to the physical and chemical properties of the two compounds, which are identical because the compounds are enantiomers.

**20. The answer is A [see VI.B.3; Table 58-2].**

The aryl sulfonamide donates a proton to behave as an acid due to the electron-withdrawing action of the aromatic ring.

**21. The answer is A [see VI.B.2].**

The  $pK_a$  (the negative log of the acid ionization constant) indicates the relative strength of an acidic drug. The lower the  $pK_a$  of an acidic drug, the stronger it is as an acid. A strong acid is defined as one that is completely ionized or dissociated in an aqueous solution; therefore, the stronger the acid, the greater the ionization.

**22. The answer is B [see III.C.2].**

The decrease in the maximal angiotensin II effect ( $E_{\max}$ ) after treatment with losartan would indicate that the number of receptors available to produce drug effect has been reduced. This occurs when antagonist interacts in an irreversible manner with the receptor and leaves only a limited number of receptors through which the agonist can only produce a less than maximal response.

23. **The answer is E** [see V.A–E].  
All of the choices except the salt form of the drug would influence the interaction of the drug with its receptor.
24. **The answer is E** [see VI.B.5].  
Flurazepam (take note of the suffix, which helps classify the compound) is a benzodiazepine and thus a basic compound. Because the pH is less than the  $pK_a$ , flurazepam is in an acidic environment and therefore exists primarily in the ionized form. The percentage ionized can be easily calculated by using the rule of nines. The  $|\text{pH} - pK_a|$  is 3, so the ratio is 99.9%:0.01% in favor of the ionized form.
25. **The answer is B** [see V.E.1.a & d].  
Enantiomers are nonsuperimposable mirror images of each other that have identical physical and chemical properties except for the rotation of plane-polarized light. Enantiomers are distinguishable in a chiral environment. Geometric isomers, diastereomers, and bioisosteres each have unique physical and chemical properties.
26. **The answer is D** [see V.B; V.D; V.E.1.c; V.E.2.b].  
The pharmacophore describes the critical organic functional groups and their spatial relationship within a drug molecule required for a specific pharmacological activity. A bioisostere is a compound containing an atom or group of atoms that is spatially and electronically similar to another molecule that produces a similar biological activity. A eutomer is one of a pair of enantiomers that has the desired pharmacological activity. The other isomer is the distomer that may not have pharmacological activity or may cause adverse effects. Epimers are a pair of compounds that have exactly the same stereochemistry in all positions except one.
27. **The answer is C** [see VI.B.4; Table 58-1; Table 58-3].  
Primary and tertiary amines are basic because they have a free pair of electrons that can accept a proton. The quaternary amines are neutral because there are no free electrons available to accept a proton. Guanidines and amidines also have free electrons to accept a proton and therefore they are basic functional groups. Amides are neutral compounds although they appear to have a free pair of electrons like the amines, but the difference is that the electrons on the amide nitrogen are in resonance with the double bond on the carbonyl, making them unavailable to accept a proton.
28. **The answer is C** [see VI.A.1].  
The partition coefficient is defined as the ratio of the solubility of an agent in an organic lipophilic solvent (i.e., *n*-octanol) to its solubility in an aqueous buffer. The functional groups present, either ionizable or non-ionizable, influence the partition coefficient.
29. **The answer is A** [see Table 58-2; VI.B.3.a, 4.a, & 6.a].  
The imide is a weak acid, so adding a strong base like sodium hydroxide (NaOH) or potassium hydroxide (KOH) will produce an inorganic salt. All the other choices (i.e., sulfuric acid, hydrochloric acid, nitric acid, and hydrobromic acid) are strong acids and would not produce a salt upon addition to the weak acid imide.
30. **The answer is E (I, II, and III)** [see III.D].  
Suicide inhibitors are drugs that are metabolized or destroyed in the process of inhibiting enzymatic activity, whereas allosteric inhibitors target a site distinct from that for the substrate. Some drugs interact irreversibly with their enzyme target due to covalent bonding.
31. **The answer is D (II, III)** [see VI.B.6].  
Almost all salts (with very few exceptions) are strong electrolytes, and the terminology *pentobarbital sodium* and *diphenhydramine hydrochloride* indicates that each compound is salt. Acetic acid is a weak acid; therefore, it is a weak electrolyte.
32. **The answer is A (I)** [see VI.B].  
When meperidine hydrochloride solution is mixed with the alkaline solution of sodium bicarbonate, a neutralization reaction occurs with the possible precipitation of the water-insoluble free base meperidine. A neutralization reaction occurs when acidic solutions are mixed with basic solutions, or conversely. No reaction, in terms of acid–base, occurs when solutions are mixed with other acidic or neutral solutions or when basic solutions are mixed with other basic or neutral solutions. There should be no reaction, then, when the meperidine hydrochloride solution, which is acidic, is mixed with the acidic solution of atropine sulfate or the neutral solution of sodium chloride.
33. **The answer is B (III)** [see VIII.B.3].  
Both epinephrine and morphine are naturally occurring, whereas fondaparinux is a synthetic derivative of heparin.
34. **The answer is A (I)** [see VI.B].  
A weakly acidic drug will be more ionized in an alkaline urine; therefore, it will be more polar and thus more soluble in the aqueous urine. It would also be less liposoluble, less likely to undergo tubular reabsorption, and thus more likely to be excreted.
35. **The answer is C (I, II)** [see VI.B; Table 58-1].  
The molecule contains a basic nitrogen, which is bonded to three carbon atoms (i.e., a tertiary amine), and an ethyl carboxylate, which is an ester group. An ester is the product of the reaction of an alcohol with a carboxylic acid that forms an alkyl carboxylate. There is no free carboxylic acid present. However, if this molecule is subjected to hydrolysis, it forms a carboxylic acid and ethyl alcohol.

- 36. The answer is B (III)** [see VI.B; Table 58-3].  
Because meperidine contains a tertiary amine, it is classified as a base; because it is an organic base, it is considered weak. The nitrogen is not protonated. It is not ionic and therefore is not a salt.
- 37. The answer is A (I)** [see VI.B].  
Alkalinization of the urine decreases the ionization of meperidine, making it more liposoluble and thus more likely to undergo reabsorption in the kidney tubule. This results in a decreased rate of excretion and an increased duration of action. The six-member, nonaromatic ring is a piperidine ring that is substituted at the 4-position (nitrogen is position 1) with a phenyl ring. The compound does not contain a piperazine ring or a propyl group.
- 38. The answer is C (I, II)** [see VIII.A].  
The cardiac glycoside digoxin occurs naturally in foxglove and strophanthus plants but it does not substitute or mimic the actions of endogenous hormones.
- 39. The answer is C** [see V.E.2].  
These molecules are isomers that have two asymmetric carbon atoms. They are not superimposable and are not mirror images; therefore, they are known as diastereomers.
- 40. The answer is B** [see V.E.1].  
These molecules are isomers that have one asymmetric carbon atom. They are nonsuperimposable mirror images; therefore, they are enantiomers.
- 41. The answer is A** [see V.E.2.c].  
These molecules have different spatial arrangements; however, these molecules do not have an asymmetric center. The presence of the double bond, which restricts the rotation of the groups on each carbon atom involved in the double bond, characterizes this type of isomerism as geometric.
- 42. The answer is D** [see V.D].  
These molecules are neither isomers nor the same compound because one contains three oxygens, whereas the other contains two oxygens and a sulfur. Because oxygen and sulfur are in the same periodic family, they are isosteric and are known as bioisosteres.
- 43. The answer is E** [see V.E.3].  
These structures are actually two views of the same compound. Rotation around the side chain single bonds connecting the ring nitrogen to the tertiary nitrogen produces these two different conformations. Thus, these are conformational isomers.

# Nuclear Pharmacy

STEPHEN C. DRAGOTAKES, JEFFREY P. NORENBURG

## I. INTRODUCTION

### A. Overview

1. **Nuclear pharmacy** is defined as a “patient-oriented service that embodies the scientific knowledge and professional judgment required to improve and promote health through the safe and efficacious use of radioactive drugs for diagnosis and therapy.”<sup>1</sup>
2. **Radiopharmaceuticals** are drugs that contain a biological moiety and a radioactive element. The biological construct targets a physiological or pathophysiological process of interest, allowing the localization of radiation that, in turn, may be imaged or used to effect therapy. Most radiopharmaceuticals are used in diagnostic medical imaging; however, they are also used in therapeutic applications, such as in the treatment of hyperthyroidism, thyroid cancer, polycythemia vera, and in the alleviation of bone pain.<sup>2</sup>
3. **Nuclear pharmacy practice** entails the following:
  - a. Procurement of radiopharmaceuticals
  - b. Compounding of radiopharmaceuticals
  - c. Performance of routine quality control procedures
  - d. Dispensing of radiopharmaceuticals
  - e. Distribution of radiopharmaceuticals
  - f. Implementation of basic radiation protection procedures and practices
  - g. Consultation with and/or education of the nuclear medicine community, patients, pharmacists, other health professionals, and the general public regarding the following:
    - (1) Physical and chemical properties of radiopharmaceuticals
    - (2) Pharmacokinetics and biodistribution of radiopharmaceuticals
    - (3) Drug interactions and other factors that alter patterns of distribution
  - h. Monitoring of patient outcomes
  - i. Research and development of radiopharmaceuticals<sup>3</sup>

### B. Properties of radiopharmaceuticals

1. **Pharmacological effects.** Typically, radiopharmaceuticals lack pharmacological effects because the mass quantities range from picogram (pg) to nanogram (ng) per kilogram (kg) of administered dose.
2. **Route of administration.** Most radiopharmaceuticals are prepared as sterile, pyrogen-free intravenous (IV) solutions or suspensions to be administered directly to the patient. Other routes of administration include intradermal, oral, interstitial, and inhalation (e.g., radioactive gases, aerosols).
3. **Radionuclides**
  - a. The radioactive component of a radiopharmaceutical is referred to as a radionuclide. Nuclides are identified as atoms having a specific number of protons and neutrons in the nucleus. A nuclide is typically identified by the chemical symbol of the element with a mass number shown as a superscript, indicating the sum of protons and neutrons (e.g., iodide-131 is indicated as <sup>131</sup>I). When the atom is radioactive, it is called a radionuclide.
  - b. Radionuclides undergo spontaneous radioactive decay accompanied by the release of energy. The distribution, metabolism, and elimination of the radiopharmaceutical can be determined

by measuring this energy with imaging equipment. There are four major types of radiation emitted through this process:  $\alpha$ ,  $\beta$ ,  $\gamma$ , and x-rays.  $\alpha$  and  $\beta$  radiations are not useful in medical imaging and are, therefore, undesirable in diagnostic applications. Most diagnostic radiopharmaceuticals use penetrating  $\gamma$ -radiation, which can be easily detected and converted into imaging data.

#### 4. Half-lives of radiopharmaceuticals

- The **physical half-life** of a radiopharmaceutical is the amount of time necessary for the radioactive atoms to decay to one-half their original number. Each radionuclide is characterized by a specific half-life that is a physical constant.
- The **biological half-life** of a radiopharmaceutical is the amount of time required for the body to metabolize or eliminate one-half of the administered dose of any substance through biological processes.
- The **effective half-life** of a radiopharmaceutical is the time required for an administered radiopharmaceutical dose to be reduced by one-half as a result of both physical decay and biological mechanisms. It is defined as  $T_e = (T_p + T_b)/(T_p \times T_b)$ , where  $T_e$  is the effective half-life,  $T_p$  is the physical half-life, and  $T_b$  is the biological half-life.

### C. Optimal radiopharmaceuticals

#### 1. Optimal diagnostic radiopharmaceuticals

- Should contain a radionuclide with a half-life short enough to minimize radiation exposure to the patient, yet long enough to allow for collection of imaging information. The optimal relationship is a physical half-life equal to approximately 67% of the biological process of interest.
- Should incorporate a  $\gamma$ -emitting radionuclide, which decays with the emission of a photon energy between 100 and 300 kiloelectron volts (keV), which is efficiently detected with current instrumentation
- Should contain a biological component that allows rapid localization in the organ system of interest and be metabolized or excreted from the nontarget tissues to maximize contrast and minimize the radiation absorbed dose to nontarget organs
- Should be readily available and cost-effective

- Optimal therapeutic radiopharmaceuticals**, in addition to 1.C.1.c–d, should contain  $\alpha$  or  $\beta$  emitting radionuclides that can effectively deliver radiation in quantities sufficient to cause the desired therapeutic effect. Such effects include apoptosis, DNA damage, or irreparable cell damage leading to tissue effects.<sup>4</sup>

## II. SODIUM PERTECHNETATE TECHNETIUM-99m ( $^{99m}\text{Tc}$ ) GENERATOR

### A. Overview

- Technetium-99m ( $^{99m}\text{Tc}$ ), the most commonly used radionuclide in diagnostic imaging today, is produced by the radioactive decay of molybdenum-99 ( $^{99}\text{Mo}$ ).
  - $^{99m}\text{Tc}$  is obtained via commercially supplied, sterile, pyrogen-free generator systems. A generator is a device used to separate a short half-life radionuclide from the longer lived parent nuclide while retaining the parent to produce more of the daughter nuclide. In this way, short half-life nuclides can be made available continuously at great distances from the sites of generator production.
  - All of the commercially supplied generators currently use  $^{99}\text{Mo}$  obtained from the fission of uranium-235 ( $^{235}\text{U}$ ). This  $^{99}\text{Mo}$  parent is absorbed on an alumina ( $\text{Al}_2\text{O}_3$ ) ion exchange column, and the  $^{99m}\text{Tc}$  formed from its decay is exchanged for the chloride ion ( $\text{Cl}^-$ ) available in the 0.9% saline eluate solution washed through the column, as the sodium pertechnetate  $\text{Na}^+(\text{^{99m}TcO}_4)^-$  forms.
- The chemical valence state of the technetium atom within the Sodium Pertechnetate molecule,  $\text{Na}^+(\text{^{99m}TcO}_4)^-$  as it is eluted from the column is +7. Typically, it must be reduced to a lower valence state before it is able to react with other compounds. Although many processes can reduce  $^{99m}\text{Tc}$ , the stannous ion ( $\text{Sn}^{++}$ ) reduction method is most commonly used in  $^{99m}\text{Tc}$  radiopharmaceutical kits.
  - A radiopharmaceutical kit consists of sterile, pyrogen-free vials containing a reducing agent, the compound to be labeled, and any additional adjuncts necessary to affect the reaction or to stabilize the labeled product.

- b. In most cases, they are lyophilized under inert atmospheres to minimize the oxidation of the reducing agent (e.g.,  $\text{Sn}^{++}$ ).
- B. Sodium pertechnetate  $^{99\text{m}}\text{Tc}$  USP** (*United States Pharmacopeia*)  $\text{Na}^{+99\text{m}}\text{TcO}_4^-$ , as eluted from a generator in 0.9% sodium chloride (NaCl) solution, is an isotonic, sterile, nonpyrogenic, diagnostic radiopharmaceutical suitable for IV injection, oral administration, and direct instillation.
1. **Physical properties**
    - a. The solution should be clear, colorless, and free of visible foreign material. The pH is 4.5–7.0.
    - b.  $\text{Na}^{+99\text{m}}\text{TcO}_4^-$  is itself a radiopharmaceutical, or it may be used to radiolabel all other  $^{99\text{m}}\text{Tc}$  radiopharmaceuticals.
  2. **Biodistribution**
    - a.  $^{99\text{m}}\text{TcO}_4^-$  is handled by the body in a fashion similar to  $^{131}\text{I}$ —that is, it is taken up and released but not organified by the thyroid.
    - b. After IV administration,  $^{99\text{m}}\text{TcO}_4^-$  concentrates in the choroid plexus, thyroid gland, salivary gland, and stomach, but remains in the circulation long enough for first-pass blood-pool studies, organ perfusion, and major vessel studies.
    - c. It is primarily excreted by the kidneys unchanged and is expressed in the urine 15% to 50% by 24 hrs.
    - d. Between 10% and 55% of the administered dose is eliminated via feces within 3 days.
  3. **Decay data**
    - a.  $^{99\text{m}}\text{Tc}$  decays by isomeric transition with a physical half-life of 6 hrs.
    - b. The primary radiation emissions are 140 keV  $\gamma$  energy photons.
  4. **Purity**
    - a. USP radionuclidic purity requires a  $^{99}\text{Mo}$  breakthrough limit of  $< 0.15 \mu\text{Ci}/\text{mCi}$  of  $^{99\text{m}}\text{Tc}$  at the time of patient administration.
    - b. USP chemical purity requires an aluminum ion ( $\text{Al}^{+3}$ ) test result of less than  $10 \mu\text{g}/\text{mL}$ .
  5. **Administration and dosage.** All of the following imaging studies are administered via IV, except nasolacrimal imaging, which is instilled into the lacrimal canal.
    - a. Brain imaging: 10 to 20 mCi (370 to 740 megabecquerels; MBq)
    - b. Thyroid imaging: 1 to 10 mCi (37 to 370 MBq)
    - c. Salivary gland imaging: 1 to 5 mCi (37 to 185 MBq)
    - d. Placenta localization: 1 to 3 mCi (37 to 111 MBq)
    - e. Blood-pool imaging: 10 to 30 mCi (370 to 740 MBq)
    - f. Urinary bladder imaging: 0.5 to 1.0 mCi (18 to 37 MBq)
    - g. Nasolacrimal imaging:  $< 100 \mu\text{Ci}$  ( $< 3.7 \text{ MBq}$ )

### III. RADIOPHARMACEUTICALS FOR CARDIOVASCULAR IMAGING

- A. Perfusion agents for cardiac imaging.** Radiopharmaceuticals are useful in cardiac imaging as agents that provide information on the regional myocardial blood perfusion. They typically are administered as part of a cardiac stress test to provide information at peak cardiac output. The patient will run on a treadmill to “stress” the heart. IV coronary vessel-dilating agents are used in place of the treadmill when the patient is not physically able to exercise. Examples of these pharmacological agents are dipyridamole, adenosine, and dobutamine. The patient will also be imaged when the heart is at “rest.”
1. **Thallous chloride thallium-201 ( $^{201}\text{Tl}$ )** is a radionuclide that is produced by a cyclotron. It is used for myocardial perfusion imaging in the diagnosis of coronary artery disease and localization of myocardial infarction.
    - a. **Biodistribution**
      - (1)  $^{201}\text{Tl}$  is a monovalent cation with distribution analogous to a potassium ion ( $\text{K}^+$ ); myocardial uptake is by active transport via the  $\text{Na}^+/\text{K}^+$ -adenosine triphosphatase (ATPase) pump.
      - (2) Biodistribution is generally proportional to organ blood flow at the time of injection, with blood clearance by myocardium, kidneys, thyroid, liver, and stomach. The remainder is distributed uniformly throughout the rest of the body.
      - (3)  $^{201}\text{Tl}$  is excreted slowly and equally in both urine and feces.

- b. Decay data**
- (1) **Physical half-life:** 73 hrs
  - (2) **Effective half-life:** 2.4 days
  - (3) **Biological half-life:** 11 days
  - (4) **Primary radiation emissions:** 68 to 80 keV x-rays and 167 and 135 keV  $\gamma$  energy photons.
- c. Administration and dosage.** IV, 2 to 4 mCi (74 to 148 MBq)
2.  **$^{99m}\text{Tc}$ -sestamibi ( $^{99m}\text{Tc}$ -MIBI)** exists as a sterile, pyrogen-free IV injection after kit reconstitution with  $\text{Na}^{+99m}\text{TcO}_4^{-}$  and heating at 100°C for 10 mins.
- a. Biodistribution**
- (1)  $^{99m}\text{Tc}$ -MIBI is a cation complex that has been found to accumulate in viable myocardium by passive diffusion into the myocyte with subsequent binding to the mitochondria within the cell.
  - (2) The major pathway for clearance of  $^{99m}\text{Tc}$ -sestamibi is the hepatobiliary system. This agent is excreted without any evidence of metabolism via urine and feces.
- b. Decay data**
- (1) **Effective half-life:** 3 hrs (myocardium)
  - (2) **Biological half-life:** 6 hrs (myocardium)
- c. Administration and dosage.** IV, 10 to 30 mCi (370 to 1110 MBq)
3.  **$^{99m}\text{Tc}$ -tetrofosmin** exists as a sterile and pyrogen-free IV injection after kit reconstitution with sodium pertechnetate  $^{99m}\text{Tc}$  injection USP.
- a. Description.**  $^{99m}\text{Tc}$ -tetrofosmin is a lipophilic, cationic  $^{99m}\text{Tc}$  complex that has been found to accumulate in viable myocardium.
- b. Biodistribution.** The major pathways for clearance of  $^{99m}\text{Tc}$ -tetrofosmin are the renal system and the hepatobiliary system with 26% of the administered dose excreted in the feces and 40% excreted in the urine within 48 hrs.
- c. Physical properties.** See II.A; II.B.3.
- d. Administration and dosage.** IV during exercise, 5 to 8 mCi (185 to 296 MBq); during rest, 15 to 24 mCi (555 to 1443 MBq)
4. **Rubidium-82 ( $^{82}\text{Rb}$ ) chloride** is a generator-produced radiopharmaceutical obtained by the decay of its accelerator-produced parent strontium ( $^{82}\text{Sr}$ ; half-life is 25 days) adsorbed on a stannous oxide column.
- a. Biodistribution**
- (1) When eluted with 0.9% NaCl at a rate of 50 mL/min, a solution of the short-lived daughter  $^{82}\text{Rb}$  is eluted from the generator for direct IV administration.
  - (2) After IV administration,  $^{82}\text{Rb}$  rapidly clears from the blood and is extracted by the myocardial tissue in a manner analogous to  $\text{K}^{+}$ .
  - (3) Myocardial activity is visualized within 1 min after administration.
- b. Decay data**
- (1) **Physical half-life:** 75 secs
  - (2) The **decay mode** is by positron emission.
  - (3) The **primary radiation emissions** are annihilation 511 keV  $\gamma$  energy photons.
  - (4) Parent  $^{82}\text{Sr}$  and contaminant  $^{85}\text{Sr}$  breakthrough must be closely monitored. Acceptable levels of strontium breakthrough are  $< 0.02 \mu\text{Ci } ^{82}\text{Sr}/\text{mCi } ^{82}\text{Rb}$  and  $< 0.2 \mu\text{Ci } ^{85}\text{Sr}/\text{mCi } ^{82}\text{Rb}$ .
- c. Administration and dosage.** IV, 30 to 60 mCi (1110 to 2220 MBq)
5. **Ammonia  $^{13}\text{N}$**  exists under a USP monograph as an on-site cyclotron-produced, sterile IV solution of  $^{13}\text{NH}_3$ , useful as a myocardial perfusion agent. After June 2012 it will be available as a FDA approved drug.
- a. Decay data**
- (1) **Physical half-life:** 10 mins
  - (2) **Decay mode:** positron emission resulting in the production of two 511 keV annihilation photons
- b. Biodistribution**
- (1) After IV injection, it circulates as  $^{13}\text{NH}_3$  but localizes into the myocytes via diffusion as  $^{13}\text{NH}_3$ . It is then metabolized to glutamine and retained by the myocytes.

- (2) After IV injection, it is cleared rapidly from the blood; < 2% of the administered dose remains 5 mins postinjection.
  - (3) It is predominantly metabolized to  $^{13}\text{N}$ -glutamine by different organs of the body.
  - (4) Between 10% and 20% is excreted via the renal system.
- c. **Administration and dosage.** IV, 15 to 20 mCi (555 to 740 MBq)
- B. Agents used to measure cardiac function.** Regional myocardial wall motion
1.  **$^{99\text{m}}\text{Tc}$ -labeled red blood cells ( $^{99\text{m}}\text{Tc}$ -RBCs)** are used for blood-pool imaging, including cardiac first-pass and gated equilibrium imaging (regional cardiac wall motion).
    - a. **Physical properties.** Autologous RBCs can be labeled by several techniques that use the  $\text{Sn}^{++}$  radiolabeling method with three general steps.
      - (1) The cells are treated with  $\text{Sn}^{++}$  to provide an intracellular source of the reducing agent. This step can be carried out with either in vivo or in vitro labeling procedures.
      - (2) The next step is the removal of excess  $\text{Sn}^{++}$  either by chemical oxidation (in vitro method) or by biological clearance (in vivo method).
      - (3) All of the methods include the addition of sodium pertechnetate ( $^{99\text{m}}\text{TcO}_4^-$ ). This  $^{99\text{m}}\text{Tc}$ , while in the  $+7$  valence state, crosses the intact erythrocyte membrane and binds to intracellular hemoglobin (Hb) after being reduced by the available intracellular  $\text{Sn}^{++}$ .
    - b. **Biodistribution.** After IV injection, the labeling RBCs distribute within the blood pool and are well maintained in the blood pool with a biexponential whole body clearance of 2.5 to 2.7 hrs and 75 to 176 hrs (e.g., major route of excretion is via the urine).
    - c. **Administration and dosage.** IV, 10 to 20 mCi (370 to 740 MBq)
  2. **Pyrophosphate injection USP and phosphates USP.** The major use for these agents in nuclear medicine is as convenient and stable sources of  $\text{Sn}^{++}$  for the labeling of autologous RBCs. In this application, the kits are reconstituted with normal saline and injected via IV.

## IV. SKELETAL IMAGING

### A. Skeletal-imaging agents

1. **Overview.**  $^{99\text{m}}\text{Tc}$ -labeled bone imaging agents are useful in the detection of bone lesions that are associated with metastatic neoplasms, metabolic disorders, and infections of the bone. The imaging advantages of  $^{99\text{m}}\text{Tc}$ , coupled with the sensitivity of bone imaging agent localization in skeletal bone hydroxyapatite, allows for detection of bone pathology before evidence is shown by conventional x-rays.
2.  **$^{99\text{m}}\text{Tc}$  bone agents.** There are many different forms of  $^{99\text{m}}\text{Tc}$  bone agents, with minor differences in their individual chemical structure. Currently used bone-imaging agents are based on either the P—C—P diphosphonate structure, including  $^{99\text{m}}\text{Tc}$ -medronate disodium and  $^{99\text{m}}\text{Tc}$ -oxidronate, or the inorganic P—O—P phosphate structure, such as  $^{99\text{m}}\text{Tc}$ -pyrophosphate. These bone agents are  $\text{S}^{++}$  reduction method kits, which exist as sterile, pyrogen-free IV radiopharmaceuticals after reconstitution with  $\text{Na}^{+99\text{m}}\text{TcO}_4^-$ .
  - a. **Physical properties**
    - (1) All of the  $^{99\text{m}}\text{Tc}$  bone-imaging agents are susceptible to radiological decomposition with reoxidation of the  $^{99\text{m}}\text{Tc}$  to a higher valence state. These agents sometimes include antioxidants (e.g., ascorbic or gentisic acid) in their formulation to improve their in vitro stability.
    - (2) They should be stored at room temperature before and after reconstitution.
  - b. **Biodistribution**
    - (1) It is believed that the localization of the diphosphonates occurs by chemisorption onto the hydroxyapatite mineral matrix of skeletal bone with uptake related to bone metabolic activity and bone blood flow.
    - (2) For  $^{99\text{m}}\text{Tc}$ -medronate disodium and  $^{99\text{m}}\text{Tc}$ -oxidronate, approximately 50% of the administered dose localizes in the skeleton, and 50% is excreted by the kidneys within the first 4 to 6 hrs after IV injection.
  - c. **Administration and dosage.** IV, 10 to 20 mCi (370 to 740 MBq)

### B. Bone marrow imaging.

 See VI.A.1; VI.A.3; VI.B.

**V. LUNG IMAGING.** Radiopharmaceuticals are used to evaluate both pulmonary perfusion and pulmonary ventilation to detect pulmonary embolism and to assess pulmonary function before pneumonectomy.

**A. Pulmonary perfusion imaging**

**1.  $^{99m}\text{Tc}$ -albumin aggregated ( $^{99m}\text{Tc}$ -MAA)**

**a. Physical properties**

- (1) The  $^{99m}\text{Tc}$ -albumin aggregated kit contains human serum albumin (HSA) that has been aggregated by heat denaturation.
- (2) This  $\text{Sn}^{++}$  reduction method kit exists as a sterile, pyrogen-free suspension of radiolabeled aggregated particles after reconstitution with  $\text{Na}^{+99m}\text{TcO}_4^{-}$ .
- (3) It should be stored at 2° to 8°C after reconstitution.

**b. Biodistribution**

- (1) After IV administration of  $^{99m}\text{Tc}$ -albumin aggregated, 80% of the radiolabeled albumin particles become trapped by capillary blockade in the pulmonary circulation.
- (2) After trapping, the particles are cleared from the lungs mainly by mechanical breakup. These smaller particles are ultimately cleared from the circulation by the reticuloendothelial system.
- (3) Particle size should be controlled—that is, 90% of the particles should be between 10 and 90  $\mu\text{m}$ , and none should be > 150  $\mu\text{m}$ , to ensure adequate trapping by the lung capillary bed but no occlusion of the large-bore vessels.
- (4) Particle number should be between 200,000 and 700,000 particles per adult dose to obtain uniform imaging data without compromising capillary blood flow. Neonates should receive < 125,000 particles.

**c. Decay data.** Biological half-life in the lung: 2 to 3 hrs

**d. Administration and dosage.** IV, 1 to 4 mCi (37 to 148 MBq)

**B. Pulmonary ventilation imaging** with radioactive gases is a routine nuclear medicine procedure that can provide valuable information about regional lung ventilation. Radiopharmaceuticals used are either radioactive gases or radioaerosols.

**1. Xenon-133 ( $^{133}\text{Xe}$ )** is supplied as a radioactive gas contained in glass septum vials to be administered by inhalation through a closed respiratory system or a spirometer. It is a by-product of  $^{235}\text{U}$  fission.

**a. Biodistribution**

- (1)  $^{133}\text{Xe}$  is a readily diffusible gas, which is neither used nor produced by the body. It passes through membranes and freely exchanges between blood and tissue, tending to concentrate more in body fat.
- (2) Inhaled  $^{133}\text{Xe}$  distributes within the alveoli and enters the pulmonary venous circulation via the capillaries; most of the absorbed  $^{133}\text{Xe}$  is returned and exhaled from the lungs after a single pass through the peripheral circulation.
- (3) In concentrations used for diagnosis, the gas is physiologically inactive.

**b. Decay data**

- (1) **Effective half-life** in the lung: 2 mins
- (2) **Physical half-life:** 5.2 days
- (3) **Decay mode:**  $\beta$  minus and  $\gamma$  decay
- (4) **Primary radiation emissions:** 100 keV  $\beta$  energy and 81 keV  $\gamma$  energy photons

**c. Administration and dosage.** Inhalation, 2 to 30 mCi (74 to 1110 MBq)

**2. Radioaerosols** have become increasingly used with the advent of nebulizers that produce particles of a consistent size necessary for uniform lung distribution.

**a. Biodistribution**

- (1)  $^{99m}\text{Tc}$ -pentetate ( $^{99m}\text{Tc}$ -DTPA) radioaerosols of approximately 0.25  $\mu\text{m}$  mass median aerodynamic diameter are useful in determining lung ventilation.
- (2) After deposition of the nebulized droplets within the airways, the  $^{99m}\text{Tc}$ -pentetate is absorbed into the pulmonary circulation.
- (3) The material is subsequently excreted by the kidneys. Clearance from the lungs is sufficiently slow to allow for imaging of the lungs in multiple projections from a single administration.

**b. Physical properties.** See II.B.3.

**c. Administration and dosage.** Inhalation, 30  $\mu\text{Ci}$  (1110 MBq)

## VI. HEPATIC IMAGING

A. **Overview.** Hepatic imaging requires the use of two different classes of radiopharmaceuticals to evaluate the two cell types responsible for hepatic function.

1. **Reticuloendothelial system imaging.** The liver, spleen, and bone marrow are evaluated with radiolabeled colloidal material, ranging in size from 0.1 to 3.0  $\mu\text{m}$ . These particles are rapidly cleared from the blood by phagocytosis by the Kupffer cells or trapped in the space of Disse, which is found between the polygonal hepatocytes and the Kupffer cells.
2. **Liver spleen imaging.** Radiopharmaceuticals are useful in imaging space-occupying primary tumors and metastatic neoplasms as well as hepatic defects caused by abscesses, cysts, and trauma.
3. **Bone marrow imaging.** Images that localize in the bone marrow are useful in the evaluation of pathologies that affect bone marrow.
4. **Hepatobiliary imaging.** Hepatocyte function can be evaluated by substances meeting requirements of molecular weight, lipophilicity, and chemical structure, to be excreted by the polygonal cells into the hepatobiliary system. Hepatobiliary-imaging radiopharmaceuticals are useful in the diagnosis of cystic duct obstruction in acute cholecystitis as well as defining postcholecystectomy anatomy and physiology.

B. **Reticuloendothelial-imaging agents**

1.  **$^{99\text{m}}\text{Tc}$ -sulfur colloid ( $^{99\text{m}}\text{Tc}_2\text{S}_7$ )** is a sterile, pyrogen-free IV radiopharmaceutical formed via a chemical reaction between  $^{99\text{m}}\text{TcO}_4^-$  and an acidified solution of sodium thiosulfate at 100°C.
  - a. **Physical properties**
    - (1)  $^{99\text{m}}\text{Tc}_2\text{S}_7$  is thought to remain in the +7 valence state as the heptasulfide coprecipitate of elemental sulfur that occurs during the reaction.
    - (2) The use of  $\text{Na}^{+99\text{m}}\text{TcO}_4^-$  with  $\text{Al}^{+3}$  levels  $> 10 \mu\text{g/mL}$  can lead to the formation of particles  $> 5 \mu\text{m}$ , which can result in lung uptake.
    - (3) Heating times should be controlled to preclude large particle formation.
  - b. **Biodistribution.** After administration, 80% to 90% of the dose is phagocytized by the Kupffer cells of the liver or trapped in the space of Disse, 5% to 10% by the spleen, and the balance by the bone marrow. The blood clearance half-life is approximately 2.5 mins. Particles are not metabolized and reside in the reticuloendothelial system for a prolonged period.
  - c. **Administration and dosage.** IV, liver/spleen: 1 to 8 mCi (37 to 296 MBq); bone marrow: 3 to 12 mCi (111 to 444 MBq)

C. **Hepatobiliary-imaging agents**

1. **Overview**
  - a. **Iminodiacetic acid (IDA) derivatives**, which are lidocaine analogs, are useful as hepatobiliary-imaging agents because of their lipophilicity, which allows them to be selectively cleared by carrier-mediated hepatocyte metabolic pathways. Because these agents share the same excretion pathway as bilirubin, patients who have increased bilirubin levels exhibit decreased hepatic clearance and an increased renal clearance. Lack of gallbladder visualization is an abnormal finding, suggesting acute cholecystitis.
  - b. **Cholecystokinetic agents**, such as sincalide and cholecystokinin, may be used to empty the contents of the gallbladder in fasting patients before injection of IDA compounds in an attempt to promote gallbladder filling and visualization. These agents can also be injected after the injection of the IDA compound to cause a visualized gallbladder to empty. Cholecystokinetic agents are used to increase the specificity and sensitivity of the imaging procedure.
  - c. **Narcotic analgesics**, such as morphine, have been used to constrict the sphincter of Oddi to produce increased intraductal pressures to promote retrograde gallbladder filling.
2.  **$^{99\text{m}}\text{Tc}$ -disofenin ( $^{99\text{m}}\text{Tc}$ -DISIDA)**
  - a. **Physical properties.** See II.B.3.
  - b. **Biodistribution**
    - (1)  $^{99\text{m}}\text{Tc}$ -DISIDA is rapidly cleared from the blood; 8% remains in the blood after 30 mins.
    - (2) Approximately 9% of the administered activity is excreted in the urine during the first 2 hrs. The remainder of the activity is cleared through the hepatobiliary system.
    - (3) Peak liver uptake is within 10 mins; peak gallbladder uptake is by 30 to 40 mins.
    - (4) Gallbladder and intestinal visualization occurs within 60 mins postadministration.

- c. **Administration and dosage.** IV, nonjaundiced patient: 1 to 5 mCi (37 to 185 MBq); IV, jaundiced patient: 3 to 8 mCi (111 to 296 MBq)
- 3.  **$^{99m}\text{Tc}$ -mebrofenin**
  - a. **Physical properties.** See II.B.3.
  - b. **Biodistribution**
    - (1)  $^{99m}\text{Tc}$ -mebrofenin is rapidly cleared from the blood; 17% remains after 10 mins. Only 1% of the administered activity is excreted in the urine within the first hours; the remainder of the activity clears through the hepatobiliary system.
    - (2) Peak liver uptake occurs within 10 mins; visualization of the hepatic duct and gallbladder, within 10 to 15 mins; then intestinal activity, within 30 to 60 mins.
  - c. **Administration and dosage.** IV, nonjaundiced patient: 2 to 5 mCi (74 to 185 MBq); IV, jaundiced patient: 3 to 10 mCi (111 to 370 MBq)

## VII. RENAL IMAGING

### A. Overview

- 1. Radiopharmaceuticals are used in renal imaging to determine renal function, renal vascular flow, and renal morphology. They are also useful for the evaluation of renal function in posttransplant patients for complications such as obstruction, infarction, leakage, tubular necrosis, and rejection.
- 2. The use of radiopharmaceuticals to determine renal function or renal morphology is based on the two physiological mechanisms responsible for excretion: glomerular filtration and tubular secretion.

### B. Agents cleared by glomerular filtration are useful in determining the glomerular filtration rate (GFR), renal artery perfusion, and the visualization of the collecting system.

#### 1. $^{99m}\text{Tc}$ -pentetate ( $^{99m}\text{Tc}$ -DTPA)

##### a. Physical properties.

 See II.B.3.

##### b. Biodistribution

- (1) After administration,  $^{99m}\text{Tc}$ -pentetate rapidly distributes throughout extracellular fluid space, from which it is rapidly cleared by glomerular filtration only.
- (2) Up to 10% may be protein bound, leading to a decrease in measured GFR.
- (3) After administration, 50% of the dose is cleared by the kidneys within 2 hrs, and up to 95% is cleared by 24 hrs.

##### c. Administration and dosage.

 IV, 10 to 20 mCi (370 to 740 MBq)

#### 2. Sodium iothalamate iodine-125 ( $^{125}\text{I}$ ) injection is a commercially supplied, sterile, pyrogen-free injection containing 1 mg sodium iothalamate per milliliter.

##### a. Biodistribution

- (1) Sodium iothalamate  $^{125}\text{I}$  is used for determination of the GFR but not for imaging because of poor imaging emissions of  $^{125}\text{I}$ .
- (2) Thyroid blockade with oral potassium iodide (KI) is suggested.

##### b. Decay data

- (1) **Physical half-life:** 59 days
- (2) **Decay mode:** by electron capture
- (3) **Primary radiation emissions:** 35 keV  $\gamma$  energy photons and x-rays

##### c. Administration and dosage.

 IV, 10 to 50  $\mu\text{Ci}$  (3.7 to 18.5 MBq)

### C. Tubular secretion agents are used to evaluate renal tubular function and measure effective renal plasma flow.

#### 1. $^{99m}\text{Tc}$ -mertiatide ( $^{99m}\text{Tc}$ -MAG3)

##### a. Description

- (1) Supplied as a sterile, pyrogen-free, lyophilized kit containing betiatide, precursor of mertiatide, and chelation adjuncts.
- (2) After the sodium pertechnetate is added to the kit, it must be heated in a hot water bath or heating block at 100°C for 10 mins to form  $^{99m}\text{Tc}$ -mertiatide from the betiatide precursor.

##### b. Biodistribution

- (1) Mertiatide is renally excreted, 90% of the administered dose is excreted within 3 hrs postinjection.

- (2) It is primarily cleared via active tubular secretion and to a small extent via glomerular filtration.
  - c. **Physical properties.** See II.B.3.
  - d. **Administration and dosage.** IV, 5 to 10 mCi (185 to 370 MBq)
- D. Renal cortical imaging agents** are used to evaluate renal anatomy because of their ability to accumulate in the kidney and provide anatomical imaging data.
- 1.  **$^{99m}\text{Tc}$ -succimer ( $^{99m}\text{Tc}$ -DMSA)**
    - a. **Physical properties**
      - (1) See II.B.3.
      - (2)  $^{99m}\text{Tc}$ -succimer complex must be allowed to incubate for 10 mins postreconstitution and must be used within 4 hrs postincubation.
    - b. **Biodistribution**
      - (1) Within 3 to 6 hrs postadministration, 40% to 50% of the dose localizes in the renal cortex, where it is taken up by the tubular cells.
      - (2) Excretion into the urine is slow; 5% to 20% is excreted within the first 2 hrs, 10% to 30% by 6 hrs, and < 40% by 24 hrs.
    - c. **Administration and dosage.** IV, 2 to 6 mCi (74 to 222 MBq)

## VIII. THYROID IMAGING

### A. Overview

- 1. The basic function of the thyroid gland is the production of thyroid hormone for the regulation of metabolism. The thyroid hormones are produced within the gland through the organification of iodine obtained from the oxidation of available iodide circulating in the blood. The inability of the body to distinguish between the isotopes of iodine provides a perfect metabolic tracer for the thyroid biochemical system.
- 2. The function of the thyroid gland can be evaluated by the uptake of  $^{131}\text{I}$  or  $^{123}\text{I}$ , allowing the detection of hypothyroidism with decreased uptake and hyperthyroidism with increased uptake.
- 3.  $^{99m}\text{TcO}_4^-$  is a monovalent anion with an ionic radius similar to iodide. As a result, the pertechnetate ion is trapped by the thyroid gland in a fashion similar to iodide. The two species are sufficiently different in that  $^{99m}\text{TcO}_4^-$  is not organified nor incorporated into thyroid hormone, and it is subsequently released unchanged.

### B. Thyroid imaging agents

- 1. **Sodium iodide iodine-123 ( $^{123}\text{I}$ )** is a radiopharmaceutical available in either solution or capsule form for oral administration. It is produced by a cyclotron.
  - a. **Biodistribution**
    - (1) Orally administered iodine is rapidly absorbed from the gastrointestinal (GI) tract; thyroid gland uptake is evident within minutes.
    - (2) Sodium iodide  $^{123}\text{I}$  is considered an ideal radiopharmaceutical for iodine uptake and imaging studies because of its short half-life and useful 159 keV primary  $\gamma$  emissions.
  - b. **Decay data**
    - (1) **Physical half-life:** 13.2 hrs
    - (2) **Biological half-life:** 3.5 days
    - (3) **Decay mode:** by electron capture
    - (4) **Primary radiation emissions:** 159 keV, 27 keV, and 529 keV  $\gamma$  energy photons
  - c. **Administration and dosage.** Oral thyroid uptake: 100 to 200  $\mu\text{Ci}$  (3.7 to 7.4 MBq); thyroid image: 100 to 500  $\mu\text{Ci}$  (3.7 to 18.5 MBq)
- 2. **Sodium iodide  $^{131}\text{I}$**  is used for thyroid uptake and imaging studies; however, it is now used less often because of the high radiation dose absorbed.
  - a. **Biodistribution**
    - (1) Orally administered iodine is rapidly absorbed from the GI tract; with thyroid gland, uptake is within minutes.
    - (2) Sodium iodide  $^{131}\text{I}$  is not considered an ideal radioiodine radiopharmaceutical for iodine uptake and imaging studies because of its long half-life, poor imaging properties, and the high radiation dose to the thyroid from its  $\beta$  decay component.

- (3) The radiation dose from the high-energy  $\beta$  particle with the imaging potential of its  $\gamma$  emissions make this radionuclide the agent of choice for therapeutic treatment of hyperthyroidism and thyroid cancer.
- b. Decay data**
- (1) **Physical half-life:** 8.08 days
  - (2) **Decay mode:** by  $\beta$  decay
  - (3) **Primary radiation emissions:** 606 keV and 333 keV  $\beta$  energy; 364 keV, 637 keV, and 284 keV  $\gamma$  energy photons
- c. Administration and dosage.**  $^{131}\text{I}$  is available as either a capsule or in solution for oral administration.
- (1) **Diagnostics**
    - (a) Thyroid uptake: 2 to 15  $\mu\text{Ci}$  (0.074 to 0.555 MBq)
    - (b) Thyroid image: 30 to 50  $\mu\text{Ci}$  (1.11 to 1.85 MBq)
    - (c) Whole-body image: 1 to 5 mCi (37 to 185 MBq)
  - (2) **Therapeutics**
    - (a) Hyperthyroidism: 10 to 30 mCi (370 to 1110 MBq)
    - (b) Thyroid carcinoma: 50 to 200 mCi (1850 to 7400 MBq)
3.  $\text{Na}^{+99\text{m}}\text{TcO}_4^-$ . See II.B.
4.  $^{201}\text{Tl}$ . Parathyroid imaging
- a. **Biodistribution.**  $^{201}\text{Tl}$  concentrates in the thyroid and also in parathyroid adenomas, which can be detected by a dual isotope subtraction technique of subtracting thyroid uptake counts from  $\text{Na}^{+99\text{m}}\text{TcO}_4^-$  to unmask nonthyroid thallium uptake counts (*see III.A.1*).
  - b. **Administration and dosage.** IV, 2 mCi (74 MBq)

## IX. BRAIN IMAGING

- A. Cerebral perfusion brain-imaging agents.** Radiopharmaceuticals for evaluating brain perfusion must possess a lipophilic partition coefficient sufficient to diffuse passively across the blood-brain barrier (BBB) almost completely within one pass of the cerebral circulation, as well as being sufficiently retained to permit data collection. The regional uptake of these agents is proportional to cerebral blood flow. This class of radiopharmaceuticals is useful in the diagnosis of altered regional blood perfusion in stroke.
1.  **$^{99\text{m}}\text{Tc}$ -exametazime ( $^{99\text{m}}\text{Tc}$ -HMPAO)** exists as a sterile, pyrogen-free IV injection after reconstitution with sodium pertechnetate *USP*, which may be stabilized with the addition of a methylene blue/phosphate buffer stabilizing solution.
    - a. **Description**
      - (1)  $^{99\text{m}}\text{Tc}$ -exametazime is a neutral, lipid-soluble complex that freely crosses the BBB. This is a relatively unstable complex, which rapidly converts to a secondary, less lipophilic complex incapable of penetrating into the brain. The *in vitro* addition of a methylene blue/phosphate buffer stabilizing solution after preparing the  $^{99\text{m}}\text{Tc}$ -exametazime will stabilize the lipid-soluble complex for 4 hrs.
      - (2) Additional limitations on kit preparation parameters require the use of high mole fraction technetium generator eluates of < 2 hrs postelution from a generator previously eluted within 24 hrs.
    - b. **Biodistribution**
      - (1)  $^{99\text{m}}\text{Tc}$ -exametazime rapidly clears from the blood, with a maximum brain uptake of 3.5% to 7.0%, and up to 2.5% remaining after 24 hrs.
      - (2) The activity is widely distributed throughout the body; 30% distributes to the GI tract.
      - (3) Within 48 hrs, 40% of the dose is excreted through the urine and 15% is eliminated via the feces.
    - c. **Physical properties.** See II.B.3.
    - d. **Administration and dosage.** IV, 10 to 20 mCi (370 to 740 MBq)
  2.  **$^{99\text{m}}\text{Tc}$ -bicisate ( $^{99\text{m}}\text{Tc}$ -ECD)**
    - a. **Description**
      - (1)  $^{99\text{m}}\text{Tc}$ -bicisate exists as a sterile, pyrogen-free IV injection after reconstitution with sodium pertechnetate  $^{99\text{m}}\text{Tc}$  *USP* and the addition of a phosphate buffer.

- (2) After reconstitution, a stable lipophilic  $^{99m}\text{Tc}$ -bicisate complex is formed, which is able to cross the BBB by passive diffusion.
- b. Biodistribution**
    - (1)  $^{99m}\text{Tc}$ -bicisate is rapidly cleared from blood; a maximum of 6.5% of the administered dose is localized in the brain, and 5.0% is left in the blood after 1 hr.
    - (2) Once located in the brain cells,  $^{99m}\text{Tc}$ -bicisate is metabolized by endogenous enzymes to a polar compound that is unable to diffuse out of the brain cells.
    - (3)  $^{99m}\text{Tc}$ -bicisate is primarily eliminated via the kidneys; 50% is excreted within 2 hrs, and 74% in 24 hrs. Hepatobiliary excretion accounts for approximately 12.5% of the administered dose after 48 hrs.
  - c. Radionuclide properties.** See II.B.3.
  - d. Administration and dosage.** IV, 10 to 30 mCi (370 to 1110 MBq)
- B. Carrier-mediated transport (cerebral metabolism) mechanisms.** These are responsible for transporting glucose across the BBB. Agents such as  $^{18}\text{F}$ -fludeoxyglucose aid in the evaluation of cerebral function by mapping the distribution of glucose metabolism.  $^{18}\text{F}$ -fludeoxyglucose is produced by a cyclotron.
- 1. Biodistribution.** Currently, there is a *USP* monograph for on-site cyclotron-produced  $^{18}\text{F}$ -fludeoxyglucose, which is a glucose analog.  $^{18}\text{F}$ -fludeoxyglucose concentrates in the brain, where it is phosphorylated but does not undergo subsequent metabolism because of the replacement of the hydroxyl group in the position 2 with a fluorine atom. It is then metabolically trapped for a sufficient time to allow imaging.
  - 2. Decay data**
    - a. Physical half-life:** 109.7 mins
    - b. Decay mode:** by positron emission
    - c. Primary radiation emissions:** 633 keV energy positrons and 511 keV  $\gamma$  energy photons
  - 3. Administration and dosage.** IV, 5 to 10 mCi (185 to 370 MBq)
- C. Cerebral neurotransmitter imaging: Fluorodopa fluorine-18 ( $^{18}\text{F}$ ) injection**
- 1. Description**
    - a.** Cerebral neurotransmitter synthesis can be studied with fluorodopa  $^{18}\text{F}$  injection. The intracerebral distribution of this neurotransmitter tracer can be used in the assessment of neurodegenerative diseases such as parkinsonism.
    - b.** Fluorodopa  $^{18}\text{F}$  injection exists under a *USP* monograph as an on-site-produced sterile IV solution of a levodopa analog in which a portion of the molecule has been replaced with  $^{18}\text{F}$ , a positron-emitting radionuclide.
  - 2. Biodistribution**
    - a.** After IV injection, plasma activity decreases to 10% of the administered dose within 5 mins after injection.
    - b.** Fluorodopa  $^{18}\text{F}$  injection is predominantly metabolized in periphery via dopa decarboxylase, and catechol-*O*-methyl transferase. To maximize brain uptake, carbidopa may be used to decrease peripheral metabolism.
    - c.** Rapid excretion via renal system as dopamine metabolites
  - 3. Radionuclide data.** See IX.B.2.
  - 4. Administration and dosage.** IV, 10 to 20 mCi (370 to 740 MBq)
- D. Cerebrospinal fluid (CSF) dynamics.** Radionuclide cisternography is useful in the evaluation of hydrocephalus and in detecting CSF leaks. In CSF imaging, the radiopharmaceutical **indium-111 pentetate** ( $^{111}\text{In}$ -DTPA) is introduced intrathecally into the spinal subarachnoid space, ascends through the basal cisterns, proceeds over the cerebral hemispheres, and eventually drains into the superior sagittal sinus.  $^{111}\text{In}$ -pentetate is commercially supplied as a sterile, pyrogen-free unit dose injection. It is produced by a cyclotron.
- 1. Biodistribution**
    - a.** After intrathecal injection, this radiopharmaceutical normally ascends to the parasagittal region within 24 hrs.
    - b.** After absorption into the bloodstream via the arachnoid villi, the major route of elimination is by kidney; 65% of the dose is excreted within 48 hrs and 85% within 72 hrs.
  - 2. Decay data**
    - a. Physical half-life:** 67 hrs
    - b. CSF biological half-life:** 12 hrs

- c. **Effective half-life:** 10 hrs
  - d. **Decay mode:** by electron capture
  - e. **Primary radiation emissions:** 171 keV and 245 keV  $\gamma$  energy photons
3. **Administration and dosage.** Intrathecal, 500  $\mu$ Ci (18.5 MBq)
- E. **Imaging dopamine transport**
1.  $^{123}\text{I}$ -ioflupane ( $^{123}\text{I}$ -DaTSCAN) is a cocaine analogue that has a high binding affinity for presynaptic dopamine transporters (DATs) in the brains of mammals, in particular the striatal region of the brain. A feature of Parkinson disease is a marked reduction in dopaminergic neurons in the striatal region.  $^{123}\text{I}$ -ioflupane is indicated for detecting loss of functional dopaminergic neuron terminals in the striatum:
    - In adult patients with clinically uncertain parkinsonian syndromes, in order to help differentiate essential tremor from parkinsonian syndromes related to idiopathic Parkinson disease, multiple system atrophy, and progressive supranuclear palsy.  $^{123}\text{I}$ -ioflupane is unable to discriminate between Parkinson disease, multiple system atrophy, and progressive supranuclear palsy.
    - In adult patients, to help differentiate probable dementia with Lewy bodies from Alzheimer disease.  $^{123}\text{I}$ -ioflupane is unable to discriminate between dementia with Lewy bodies and Parkinson disease dementia.
  2. **Biodistribution**  
Ioflupane ( $^{123}\text{I}$ ) is cleared rapidly from the blood after intravenous injection; only 5% of the administered activity remains in whole blood at 5 mins postinjection. Uptake in the brain is rapid, reaching about 7% of injected activity at 10 mins postinjection and decreasing to 3% after 5 hrs. About 30% of the whole brain activity is attributed to striatal uptake. At 48 hrs postinjection, approximately 60% of the injected radioactivity is excreted in the urine, with fecal excretion calculated at approximately 14%.
  3. **Decay data**
    - a. **Physical half-life:** 13.2 hrs
    - b. **Biological half-life:** 3.5 days
    - c. **Decay mode:** by electron capture
    - d. **Primary radiation emissions:** 159 keV, 27 keV, and 529 keV  $\gamma$  energy photons

**X. INFECTION AND INFLAMMATION.** Evaluation of sites of infection include the use of agents that can associate with components of the natural defense mechanisms and can accumulate where they localize.

A. **Gallium ( $^{67}\text{Ga}$ ) citrate**

1. **Description**
  - a. It is supplied as a sterile, pyrogen-free radiopharmaceutical with preservatives.
  - b. The mechanism of localization is thought to depend on the formation of a gallium transferrin complex in the blood and on binding to transferrin receptors associated with infection and inflammation.
  - c. It accumulates in areas of white blood cell (WBC) localization.
2. **Biodistribution**
  - a. After administration, the highest concentration of  $^{67}\text{Ga}$  citrate, other than at the site of infection, is in the renal cortex. After 24 hrs, the maximum concentration shifts to bone and lymph nodes; but after 1 week, it is mainly concentrated in the liver and spleen.
  - b.  $^{67}\text{Ga}$  citrate is excreted slowly from the body; 26% is via urine, and 9% is via feces. Whole body retention is 65% after 7 days.
3. **Radionuclide data**
  - a. **Mode of production:** by cyclotron
  - b. **Decay mode:** by electron capture
  - c. **Physical half-life:** 78 hrs
  - d. **Decay emissions:** 93 keV, 185 keV, 300 keV, and 393 keV  $\gamma$  photons
4. **Administration and dosage.** IV, for infection, 3 to 8 mCi (111 to 300 MBq). A daily laxative or an enema should be used by the patient after the injection and before the images to cleanse the bowel of radioactivity that may interfere with the images and possibly lead to a false-positive result.

**B. WBC labeling agents.** Radiolabeled WBCs are used in the detection of a wide variety of infectious and inflammatory processes. Current use includes the diagnosis of intra-abdominal abscesses, inflammatory bowel disease, appendicitis, fever of unknown origin, and osteomyelitis. WBCs can be radiolabeled with  $^{111}\text{In}$ -oxine or  $^{99\text{m}}\text{Tc}$ -exametazime.

**1.  $^{111}\text{In}$ -oxyquinoline solution ( $^{111}\text{In}$ -oxine)**

**a. Description**

- (1)  $^{111}\text{In}$ -oxyquinoline is supplied as a sterile preservative-free, pyrogen-free, radiopharmaceutical solution for use in the radiolabeling of autologous leukocytes.
- (2)  $^{111}\text{In}$  forms a saturated neutral lipophilic complex with oxyquinoline (1:3 ratio), which enables it to penetrate a cell membrane.
- (3) After incubation of  $^{111}\text{In}$ -oxyquinoline with a population of autologous leukocytes, the  $^{111}\text{In}$  is thought to become firmly bound to cytoplasmic components, thereby allowing the free oxine to be released by the cell.

**b. Biodistribution**

- (1) After radiolabeling, the autologous leukocytes are reinjected; 30% is taken up by the spleen, and 30% is taken up by the liver, reaching a peak at 2 to 4 hrs postinjection.
- (2) Pulmonary uptake is immediately evident postinjection, but it clears, with minimal visible activity, after 4 hrs.
- (3) There is a biexponential blood clearance; 9% to 24% clears with a biological half-life of 2 to 5 hrs, and the remaining 13% to 18% clears with a biological half-life of 64 to 116 hrs.
- (4) Elimination is mainly through radioactive decay; < 1% is excreted in feces and urine during the first 24 hrs.

**c. Radionuclide data**

- (1) **Mode of production:** by cyclotron
- (2) **Decay mode:** by electron capture
- (3) **Physical half-life:** 67 hrs
- (4) **Decay emissions:** 245 keV and 171 keV

**d. Administration and dosage.** IV, 200 to 500  $\mu\text{Ci}$  (7.4 to 8.5 MBq)

**2.  $^{99\text{m}}\text{Tc}$ -HMPAO.** As a sterile and pyrogen-free IV injection after reconstitution with sodium pertechnetate,  $^{99\text{m}}\text{Tc}$ -HMPAO may be used to radiolabel leukocytes.

**a. Description**

- (1)  $^{99\text{m}}\text{Tc}$ -HMPAO is a neutral, lipid-soluble complex that is able to penetrate the WBC membrane. This lipophilic complex is relatively unstable and rapidly converts to a secondary complex incapable of penetrating the WBCs.
- (2) The methylene blue/phosphate buffer-stabilized solution is not able to radiolabel cells and should not be used.
- (3) Additional limitations on kit preparation parameters require the use of high mole fraction technetium generator elutes of < 2 hrs postelution from a generator previously eluted within 24 hrs.

**b. Biodistribution**

- (1) After IV injection, the radiolabeled cells localize in the lungs, liver, spleen, blood pool, bone marrow, and bladder.
- (2) Elimination is primarily via the liver.

**c. Radionuclide data.** See II.B.1.b; II.B.3.a–b.

**d. Administration and dosage.** IV, for infection, 7 to 25 mCi (260 to 925 MBq)

## XI. BREAST IMAGING

**A.  $^{99\text{m}}\text{Tc}$ -sestamibi ( $^{99\text{m}}\text{Tc}$ -MIBI)** exists as a sterile, pyrogen-free IV injection after kit reconstitution with  $\text{Na}^{+99\text{m}}\text{TcO}_4^{-}$

**1. Description**

- a.**  $^{99\text{m}}\text{Tc}$ -MIBI is used for both breast and cardiac imaging.
- b.**  $^{99\text{m}}\text{Tc}$ -MIBI is indicated for planar imaging as a second line of evaluating breast lesions in patients with an abnormal mammogram or a palpable breast mass.
- c.**  $^{99\text{m}}\text{Tc}$ -MIBI may not be used to screen for breast cancer, to confirm the presence or absence of malignancy, or to replace a biopsy.

2. **Biodistribution.**  $^{99m}\text{Tc}$ -MIBI is primarily excreted by the hepatobiliary system.
3. **Physical properties.** See II.B.3.
4. **Administration and dosage.** IV, 20 to 30 mCi (740 to 1110 MBq)

## XII. TUMORS

- A. The usefulness of radiopharmaceuticals in the detection of tumors varies in sensitivity and specificity, with differences in tumor location and type.
1. **Gallium ( $^{67}\text{Ga}$ ) citrate**
    - a. **Description**
      - (1)  $^{67}\text{Ga}$  is supplied as a sterile, pyrogen-free radiopharmaceutical with preservatives.
      - (2) The mechanism of localization is thought to depend on the formation of a gallium transferrin complex or binding to transferrin receptors on tumor cells.
      - (3) It accumulates in primary metastatic tumor sites and may detect the presence of Hodgkin disease, lymphoma, and bronchogenic carcinoma.
    - b. **Biodistribution.** See X.A.2.
    - c. **Radionuclide data.** See X.A.3.
    - d. **Administration and dosage.** IV, for tumor, 10 mCi (370 MBq)
  2.  **$^{111}\text{In}$ -pentetretotide**
    - a. **Description**
      - (1) It is supplied as a sterile, pyrogen-free kit for the preparation of  $^{111}\text{In}$ -pentetretotide. The two-component kit consists of a reaction vial containing a lyophilized mixture of pentetretotide with stabilizer adjuvants and a second vial containing an  $^{111}\text{In}$ -chloride/ferric chloride solution.
        - (a) The pentetretotide molecule is a conjugate of pentetate (diethylenetriamine pentaacetic acid; DTPA) and octreotide, which is a somatostatin analog.
        - (b)  $^{111}\text{In}$ -pentetretotide is prepared by adding the  $^{111}\text{In}/\text{Fe}$ -chloride solution to the vial containing the pentetretotide. The pentetate portion of the molecule acts as a bifunctional chelate, linking the  $^{111}\text{In}$ -radionuclide to the biologically active octreotide portion of the agent.
      - (2)  $^{111}\text{In}$ -pentetretotide is indicated for localization of primary and metastatic neuroendocrine tumors expressing somatostatin receptors.
    - b. **Biodistribution**
      - (1) Within 1 hr after IV injection,  $^{111}\text{In}$ -pentetretotide distributes from the plasma to extravascular space; less than one-third of the administered dose remains in the plasma 10 mins postinjection.
      - (2)  $^{111}\text{In}$ -pentetretotide localizes as a function of somatostatin receptor density, with accumulation in normal pituitary, thyroid, liver, spleen, and the urinary bladder.
      - (3) Elimination is primarily renal; 50% of the administered dose is excreted within 6 hrs postinjection; 85% after 24 hrs, and < 90% after 48 hrs. Less than 2% of the administered dose is cleared via the feces within 72 hrs postinjection.
    - c. **Radionuclide data**
      - (1) **Mode of production:** by cyclotron
      - (2) **Decay mode:** by electron capture
      - (3) **Physical half-life:** 67 hrs
      - (4) **Decay emissions:** 245 keV and 171 keV
    - d. **Administration and dosage.** IV, 3 to 6 mCi (111 to 222 MBq)
  3. **Iobenguane  $^{131}\text{I}$  injection ( $^{131}\text{I}$ -MIBG)**
    - a. **Description**
      - (1) It is supplied as a sterile, pyrogen-free radiopharmaceutical for use as an adjunctive diagnostic agent for the localization of primary and metastatic pheochromocytomas and neuroblastomas.
      - (2) Iobenguane (metaiodobenzylguanidine) labeled with  $^{131}\text{I}$  acts as a physiological analog of norepinephrine and is transported and accumulated in the adrenal medulla. This allows for the detection of neuroendocrine tumors via the specific uptake of labeled iobenguane.
      - (3) Because of its physiological similarities to norepinephrine, many classes of drugs that interfere with catecholamine transport and function may affect the uptake and localization of labeled iobenguane.

**b. Biodistribution**

- (1) After IV injection, there is rapid uptake in the liver, with lesser amounts accumulating in the lungs, heart, and spleen.
- (2) Normal adrenal gland uptake is low; but for tumors such as pheochromocytomas and neuroblastomas, the uptake is relatively higher.
- (3) Elimination is renal; most of the drug is excreted mainly unchanged. Between 40% and 50% of the administered dose is excreted within 24 hrs, and 70% to 90% is excreted within 4 days postinjection.
- (4) Administration of potassium iodide 1 day before and for 10 days after administration is suggested to reduce thyroid uptake of potential radioiodine contaminants.

**c. Physical data.** See VIII.B.2.b.**d. Administration and dosage.** IV, 0.5 to 1.0 mCi (18.5 to 37.0 MBq)

4. **<sup>201</sup>Tl.** This agent has utility as a tumor-imaging agent because of its accumulation in the rapidly metabolizing cells of certain tumors in accordance with its mechanism of localization (see III.A.1).

**a. Administration and dosage.** IV, 1.5 to 3.0 mCi (55 to 111 MBq)

5. **<sup>18</sup>F-fludeoxyglucose USP.** Currently, there is a USP monograph for on-site cyclotron-produced <sup>18</sup>F-fludeoxyglucose, which is a glucose analog. This agent has utility as a tumor-imaging agent because of an increased demand for glucose by tumors with an advanced state of malignancy. Not only can <sup>18</sup>F-fludeoxyglucose locate and differentiate tumors, but it can also help distinguish between recurrent brain tumor and radiation necrosis in patients receiving radiation therapy (see IX.B).

**a. Biodistribution.** <sup>18</sup>F-fludeoxyglucose concentrates in metabolically active cells, where it is phosphorylated but does not undergo subsequent metabolism because of the replacement of the hydroxyl group in the position 2 with a fluorine atom. It is then metabolically trapped for a sufficient time to allow imaging.**b. Administration and dosage.** IV, 5 to 25 mCi (185 to 370 MBq)

- B. **Antibodies.** See XIV. D. Yttrium-90 ibritumomab tiuxetan & Indium-111 ibritumomab tiuxetan B.2. See XIVE. Iodine I-131 tositumomab.

**XIII. THERAPEUTIC AGENTS.** The therapeutic use of radiopharmaceuticals is based on the concept of selective localization of radiopharmaceuticals coupled with the lethality of the same because of the tissue damage resulting from highly ionizing particulate emissions such as  $\beta$  particles.

**A. Sodium iodide <sup>131</sup>I (therapeutic)****1. Description**

- a. It is indicated for treatment of hyperthyroidism and thyroid carcinoma.
- b. Its therapeutic action is owing to the accumulation and retention of iodine and its isotope <sup>131</sup>I.

**2. Biodistribution**

- a. See VIII.A; VIII.B.2.
- b. **Biological half-life in the thyroid:** euthyroid patient, 80 days; hyperthyroid patient, 5 to 40 days

**3. Radionuclide data.** See VIII.B.2.b.**4. Administration and dosage.** Oral capsule or oral solution

- a. Hyperthyroidism: 10 to 30 mCi (370 to 1110 MBq)
- b. Thyroid carcinoma: 30 to 200 mCi (1110 to 7400 MBq)

**B. Strontium-89 (<sup>89</sup>Sr) chloride****1. Description**

- a. It is indicated for the alleviation of bone pain arising from metastatic bone disease.
- b. As a metabolic analog of calcium, <sup>89</sup>Sr concentrates selectively in areas of increased osteogenesis, thus delivering a radiation dose sufficient to provide a palliative effect.
- c. Pain relief begins 7 to 21 days after administration, with maximum relief by 6 weeks and an average duration of 6 months.
- d. Reduction in patient analgesic usage occurs in up to 75% of patients treated; complete pain relief is seen in 20% of treated patients, and no pain relief in 20% to 25% of treated patients.
- e. Bone marrow suppression effects limit <sup>89</sup>Sr use to patients with initial WBC counts > 2400 and platelet counts > 60,000.

2. **Biodistribution**
    - a. After administration,  $^{89}\text{Sr}$  clears rapidly from blood and localizes in the bone hydroxyapatite.
    - b. Initial biological half-life in normal bone is 14 days; longer retention is seen in metastatic bone lesions. Between 12% and 90% of the administered dose is retained for up to 3 months after administration.
    - c. Elimination is primarily renal; 66% of the administered dose clears via GFR within the first 2 days, and 33% is excreted via feces.
  3. **Radionuclide data**
    - a. **Mode of production:** by accelerator
    - b. **Decay mode:** by  $\beta$
    - c. **Emission data:** 1.46 MeV maximum  $\beta$  energy, 100% abundance
    - d. **Physical half-life:** 50.5 days
  4. **Administration and dosage.** IV, 4 mCi (148 MBq), 40 to 60  $\mu\text{Ci}/\text{kg}$  (1.5 to 2.2 MBq/kg)
- C. **Samarium-153 ( $^{153}\text{Sm}$ ) lexidronam**
1. **Description**
    - a.  $^{153}\text{Sm}$  is indicated for the relief of pain in patients who have confirmed metastatic cancer of the bone.
    - b.  $^{153}\text{Sm}$  concentrates in areas of high bone turnover and accumulates more in osteoblastic lesions than in the normal bone.
    - c. The goal of  $^{153}\text{Sm}$  therapy is for patients to be able to reduce the amount of narcotic analgesics needed to control their pain.
  2. **Biodistribution**
    - a. The lesion to normal bone ratio is 5:1.
    - b. The percentage of uptake of  $^{153}\text{Sm}$  is directly proportional to the number of lesions the patient has.
    - c. Less than 1% of the dose remains in the blood 5 hrs postinjection.
    - d.  $^{153}\text{Sm}$  is 100% renally excreted over 12 hrs.
    - e. The onset is approximately 1 week.
  3. **Radionuclide data**
    - a. **Mode of production:** by cyclotron
    - b. **Decay mode:** by  $\beta$  and  $\gamma$  decay
    - c. **Physical half-life:** 46.3 hrs
    - d. **Decay emissions:** 640 keV, 710 keV, and 840 keV  $\beta$  energy and 103 keV  $\gamma$  energy photons
  4. **Precautions.**  $^{153}\text{Sm}$  may cause bone marrow suppression, which should return to baseline within 8 weeks postinjection.
  5. **Administration and dosage.** IV, 1 mCi/kg (37 MBq/kg)
- D. **Yttrium-90 ( $^{90}\text{Y}$ ) ibritumomab tiuxetan and  $^{111}\text{In}$ -ibritumomab tiuxetan**
1. **Overview**
    - a.  $^{111}\text{In}$ -ibritumomab tiuxetan and  $^{90}\text{Y}$ -ibritumomab tiuxetan are part of a therapeutic regimen used in the treatment of non-Hodgkin lymphoma (NHL) patients with relapsed refractory low-grade, follicular, or transformed B cell NHL and patients with rituximab refractory NHL.
    - b. Ibritumomab tiuxetan is an immunoconjugate consisting of a monoclonal antibody ibritumomab, which is linked to the chelator tiuxetan.
    - c. The ibritumomab antibody is a murine immunoglobulin G1 (IgG1)  $\kappa$  monoclonal antibody produced in Chinese hamster ovary (CHO) cells. The ibritumomab antibody is directed against the CD20 antigen, which is expressed on the surface of normal and malignant B lymphocytes.
    - d. The linker-chelator tiuxetan provides a high-affinity chelation site for  $^{111}\text{In}$  in the case of the imaging dose and for  $^{90}\text{Y}$  in the case of the therapeutic dose.
    - e. The therapeutic regimen is administered in two separate doses. This allows for the qualitative evaluation of the biodistribution to avoid potential toxicities such as abnormally high bone marrow localization or prolonged renal excretion. In each administration, patients must be premedicated with diphenhydramine (50 mg) and acetaminophen (50 mg) 0.5 hr before receiving the rituximab infusion required before administering the radiolabeled antibody.
      - (1) Step 1 is the administration of rituximab followed by the  $^{111}\text{In}$ -ibritumomab tiuxetan diagnostic imaging dose.

- (2) Step 2 follows step 1 by 7 to 9 days and consists of a second rituximab infusion followed by the  $^{90}\text{Y}$ -ibritumomab therapy dose.
2. **Description**
    - a. Supplied as two separate kits to produce a single dose of  $^{111}\text{In}$ -ibritumomab tiuxetan and a single dose of  $^{90}\text{Y}$ -ibritumomab tiuxetan
    - b. Each kit consists of four vials containing:
      - (1) Ibritumomab tiuxetan in saline, 3.2 mg
      - (2) Sodium acetate, 50 mM
      - (3) Formulation buffer (contains human serum albumin)
      - (4) One empty reaction vial
    - c. Exists as a sterile, nonpyrogenic IV solution after formulation with either  $^{111}\text{In}$  or  $^{90}\text{Y}$
  3. **Biodistribution**
    - a. The mean half-life for  $^{90}\text{Y}$ -ibritumomab tiuxetan in the blood is 30 hrs.
    - b. Approximately 7.8% of the administered dose is excreted in the urine over 7 days.
    - c. The estimated biological half-life is 48 hrs.
  4. **Radionuclide data**
    - a.  $^{111}\text{In}$ . See XIII.B.1.c.
    - b.  $^{90}\text{Y}$ 
      - (1) **Mode of production:** by reactor
      - (2) **Decay mode:** by  $\beta$
      - (3) **Physical half-life:** 64.1 hrs
      - (4) **Decay emission:** 935 mean keV, 100% emission
  5. **Precautions**
    - a.  $^{90}\text{Y}$ -ibritumomab tiuxetan should not be administered to patients with altered biodistributions of the  $^{111}\text{In}$ -ibritumomab tiuxetan imaging and dosimetry.
    - b.  $^{90}\text{Y}$ -ibritumomab tiuxetan should not be administered to patients with:
      - (1)  $\leq 25\%$  lymphoma marrow involvement
      - (2) Platelet count  $< 100,000$  cells/ $\text{mm}^3$
      - (3) Neutrophil count  $< 1500$  cells/ $\text{mm}^3$
      - (4) Hypocellular bone marrow
      - (5) History of failed stem cell collection
    - c. Ibritumomab tiuxetan is contraindicated in patients with known hypersensitivity or anaphylactic reactions to murine proteins.
    - d. Patients who have previously received murine-based protein therapy should be screened for human antimouse antibodies.
    - e. Infusion-related adverse events, including asthenia, chills, and nausea, are common and are usually self-limited. Tumor lysis syndrome has been reported after rituximab infusions, which are part of  $^{90}\text{Y}$ -ibritumomab tiuxetan therapy. Patients should be monitored closely for this potentially fatal adverse event.

# Study Questions

**Directions for questions 1–7:** Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by one of the suggested answers or phrases. Choose the best answer.

- Which of the following emissions from the decay of radionuclides is most commonly used in nuclear medicine diagnostic imaging?
  - x-ray
  - $\beta$
  - $\alpha$
  - $\gamma$
  - positron
- Which of the following radionuclides is most commonly used in nuclear pharmacy practice?
  - gallium-67 ( $^{67}\text{Ga}$ )
  - thallium-201 ( $^{201}\text{Tl}$ )
  - technetium-99m ( $^{99\text{m}}\text{Tc}$ )
  - iodine-123 ( $^{123}\text{I}$ )
  - xenon-133 ( $^{133}\text{Xe}$ )
- Which of the following radionuclides is produced using a generator?
  - technetium-99m ( $^{99\text{m}}\text{Tc}$ )
  - thallium-201 ( $^{201}\text{Tl}$ )
  - gallium-67 ( $^{67}\text{Ga}$ )
  - xenon-133 ( $^{133}\text{Xe}$ )
  - iodine-123 ( $^{123}\text{I}$ )
- Which of the following radiopharmaceuticals can be used in skeletal imaging?
  - $^{99\text{m}}\text{Tc}$  albumin aggregated
  - $^{99\text{m}}\text{Tc}$  medronate disodium
  - xenon-133 gas *USP*
  - thallous chloride ( $^{201}\text{Tl}$ ) *USP*
  - $^{99\text{m}}\text{Tc}$  disofenin
- Which of the following radiopharmaceuticals is used in the diagnosis of acute cholecystitis?
  - $^{99\text{m}}\text{Tc}$  sulfur colloid
  - $^{99\text{m}}\text{Tc}$  medronate disodium
  - $^{99\text{m}}\text{Tc}$  albumin
  - $^{99\text{m}}\text{Tc}$  exametazime
  - $^{99\text{m}}\text{Tc}$  disofenin

- Which of the following cyclotron-produced radiopharmaceuticals is used for assessing regional myocardial perfusion as part of an exercise stress test?
  - thallous chloride  $^{201}\text{Tl}$  *USP*
  - sodium iodide  $^{123}\text{I}$
  - gallium citrate  $^{67}\text{Ga}$  *USP*
  - $^{111}\text{In}$  pentetate
  - $^{57}\text{Co}$  cyanocobalamin
- Glomerular filtration and the urinary collection system can best be evaluated using which of the following agents?
  - $^{99\text{m}}\text{Tc}$  sulfur colloid
  - $^{99\text{m}}\text{Tc}$  albumin
  - $^{99\text{m}}\text{Tc}$  sestamibi
  - $^{99\text{m}}\text{Tc}$  disofenin
  - $^{99\text{m}}\text{Tc}$  pentetate

**Directions for questions 8–11:** The questions and incomplete statements in this section can be correctly answered or completed by one or more of the suggested answers. Choose the answer, A–E.

- if **I only** is correct
  - if **III only** is correct
  - if **I and II** are correct
  - if **II and III** are correct
  - if **I, II, and III** are correct
- The definition of the optimal radiopharmaceutical includes which of the following attributes?
    - short half-life
    - photon with a 100–300 keV energy
    - rapid localization in target tissue and quick clearance from nontarget tissue
  - Which of the following statements are true for sodium pertechnetate technetium-99m ( $^{99\text{m}}\text{Tc}$ ) *USP*?
    - It is used to radiolabel all other  $^{99\text{m}}\text{Tc}$  radiopharmaceuticals.
    - The molybdenum-99 ( $^{99}\text{Mo}$ ) breakthrough limit is  $< 0.15 \mu\text{Ci } ^{99}\text{Mo}/\text{mCi } ^{99\text{m}}\text{Tc}$  ( $< 0.15 \text{ kBq}/\text{MBq}$ ).
    - It has a physical half-life of 16 hrs.
  - Which of the following organs can be imaged with technetium-99m ( $^{99\text{m}}\text{Tc}$ ) sulfur colloid?
    - liver
    - spleen
    - bone marrow

11. Which of the following radiopharmaceuticals may be used to image the thyroid gland?

- I. sodium iodide  $^{131}\text{I}$
- II. sodium pertechnetate  $^{99\text{m}}\text{Tc USP}$
- III. sodium iodide  $^{123}\text{I}$

**Directions for questions 12–16:** Each of the following mechanisms of localization is most closely related to one of the following radiopharmaceuticals. The mechanisms may be used more than once or not at all. Choose the best answer, A–E.

- A metabolic trapping
- B phagocytosis
- C capillary blockade
- D active transport
- E passive diffusion

12. thallos chloride  $^{201}\text{Tl USP}$

13.  $^{99\text{m}}\text{Tc}$  albumin aggregated *USP*

14.  $^{99\text{m}}\text{Tc}$  sulfur colloid

15.  $^{99\text{m}}\text{Tc}$  exametazime

16.  $^{18}\text{F}$  fludeoxyglucose

## Answers and Explanations

1. **The answer is D** [see I.B.3.b].

Current camera technology most efficiently detects  $\gamma$  radiation.  $\alpha$  and  $\beta$  emissions are not useful in nuclear medicine imaging because of their harmful particulate emissions and low tissue penetration. Although x-ray emissions can be used as in the case of the mercury daughter of the thallos chloride  $^{201}\text{Tl}$  parent, they are not efficiently detected. Annihilation radiation associated with positron decay can be imaged, but this technology is currently limited to a few specialized centers.

2. **The answer is C** [see II.A.1].

$^{99\text{m}}\text{Tc}$  has become the radionuclide of choice in current nuclear pharmacy practice since its introduction in the mid-1960s.  $^{99\text{m}}\text{Tc}$  fulfills all of the requirements of the optimal radiopharmaceutical, with its physical half-life of 6 hrs, 140 keV  $\gamma$  energy emission, ready availability, cost, and ability to be radiolabeled to various biologically active compounds.

3. **The answer is A** [see II.A.1.a].

$^{99\text{m}}\text{Tc}$  is obtained via commercially supplied, sterile, pyrogen-free generator systems. A generator is a device used to separate a short half-life radionuclide from the longer lived parent nuclide, while retaining the parent to produce more of the daughter nuclide. In this way, short-half-life nuclides can be made available on a continuous basis at great distances from the sites of generator production.

4. **The answer is B** [see IV.A.2].

The  $^{99\text{m}}\text{Tc}$ -diphosphonate compounds are the most popular bone-imaging agents currently used in nuclear medicine imaging. They are rapidly taken up by skeletal bone; 50% of the administered dose is adsorbed onto bone hydroxyapatite and the remainder is excreted by the kidneys. The imaging advantages of the  $^{99\text{m}}\text{Tc}$ , coupled with the sensitivity of bone agent localization in skeletal bone hydroxyapatite, allow for detection of bone pathology before evidence of pathology can be shown by conventional x-ray.

5. **The answer is E** [see VI.C.1–2].

$^{99\text{m}}\text{Tc}$ -disofenin is an iminodiacetic acid derivative, which is useful for hepatobiliary imaging due to its ability to be selectively cleared by a carrier-mediated hepatocyte pathway. Lack of gallbladder visualization is an abnormal finding suggestive of acute cholecystitis.

6. **The answer is A** [see III.A.1].

Regional uptake of thallos chloride  $^{201}\text{Tl USP}$  is proportional to myocardial blood supply. The injection of  $^{201}\text{Tl}$  in concert with a treadmill exercise stress test determines myocardial perfusion at maximum cardiac output when cardiac demand outstrips supply and the distribution of  $^{201}\text{Tl}$  is less after affected by collateral blood supply within the myocardium. Regions that do not take up  $^{201}\text{Tl}$  are interpreted as areas of infarct or ischemia. If these focal areas of decreased uptake subsequently fill in with redistributed  $^{201}\text{Tl}$ , they are interpreted to be areas of ischemia, in contrast with areas of infarct, which remain as diminished areas of activity.

**7. The answer is E [see VII.B.1].**

<sup>99m</sup>Tc-pentetate is cleared through glomerular filtration in the same manner as inulin and can be used to determine the GFR as well as in the evaluation of obstruction of vascular supply and renal morphology.

**8. The answer is E (I, II, III) [see I.C].**

The optimal radiopharmaceutical has a half-life short enough to minimize radiation exposure to the patient yet long enough to allow for collection of imaging information. It should incorporate a  $\gamma$ -emitting radionuclide, which decays with the emission of a photon energy between 100 and 300 keV, which is efficiently detected with current instrumentation. The radiopharmaceutical should localize rapidly in the organ system of interest and be metabolized, excreted, or both from the nontarget tissues to maximize contrast and minimize radiation-absorbed dose.

**9. The answer is C (I, II) [see II.A–B].**

Sodium pertechnetate <sup>99m</sup>Tc USP decays by isomeric transition and has a physical half-life of 6 hrs. The emission of a  $\gamma$  photon has the energy of 140 keV.

**10. The answer is E (I, II, III) [see VI.B.1].**

<sup>99m</sup>Tc-sulfur colloid localizes within the reticuloendothelial system, 80% to 90% of the dose is phagocytized by the Kupffer cells of the liver, 5% to 10% by the spleen, and the balance by the bone marrow.

**11. The answer is E (I, II, III) [see VIII.B].**

Although all of the listed agents accumulate in the thyroid gland, only sodium iodide <sup>123</sup>I possesses ideal imaging characteristics and organification into thyroid hormone. Although the imaging properties of sodium pertechnetate <sup>99m</sup>Tc USP are good, the pertechnetate ion is trapped only by the thyroid and not organified, thus limiting the information provided by the image.

**12. The answer is D [see III.A.1].**

Thallos chloride <sup>201</sup>Tl USP is a monovalent cation with distribution analogous to potassium ion (K<sup>+</sup>). Myocardial uptake is by active transport via the Na<sup>+</sup>/K<sup>+</sup>-ATPase pump.

**13. The answer is C [see V.A.1].**

After IV administration of <sup>99m</sup>Tc-albumin aggregated USP, 80% of the radiolabeled albumin particles become trapped by capillary blockade in the pulmonary circulation.

**14. The answer is B [see VI.B.1].**

After the administration of <sup>99m</sup>Tc-sulfur colloid, 80% to 90% of the dose is phagocytized by the Kupffer cells of the liver, 5% to 10% by the spleen, and the balance by the bone marrow.

**15. The answer is E [see IX.A.1].**

<sup>99m</sup>Tc-exametazime is used for evaluating brain perfusion. It possesses a lipophilic partition coefficient that is sufficient to diffuse passively across the BBB almost completely within one pass of the cerebral circulation, and that is sufficiently retained to permit data collection.

**16. The answer is A [see IX.B.1].**

<sup>18</sup>F-fludeoxyglucose is used in evaluating cerebral function by mapping the distribution of cerebral glucose metabolism. As an analog of glucose, <sup>18</sup>F-fludeoxyglucose is transported into the brain by carrier-mediated transport mechanisms responsible for transporting glucose across the BBB. Because the presence of the fluorine atom in the position 2 prevents metabolism beyond the phosphorylation step, <sup>18</sup>F-fludeoxyglucose becomes metabolically trapped within the brain.

# Medication Therapy Management

PENNY S. SHELTON, K. PAIGE D. BROWN

## I. INTRODUCTION

- A. Pharmacists and patient outcomes.** Since the coining of the term *pharmaceutical care* in 1990,<sup>1</sup> pharmacists in all settings have taken on greater responsibility for patient outcomes. Several terms have been used to describe the pharmacist's nondispensary role in patient care: clinical or cognitive services, pharmaceutical care, and now medication therapy management (MTM). Regardless of the term used or the setting in which care is provided, pharmacy practice should be proactive and patient-centric to ensure quality patient care.
- B. Definition.** In 2005, a definition for MTM was reached by consensus among 11 national pharmacy organizations.<sup>2</sup> Essentially, medication therapy management services (MTMS) are a broad range of patient-specific services designed to improve quality of care and continuity of care, as well as optimize treatment outcomes.
- C. Medicare Part D and MTM.** In 2006, the Medicare Modernization Act (MMA) of 2003<sup>3</sup> was implemented, providing prescription drug coverage (Part D). The MMA has additional historical significance in that MTM was mandated for eligible Medicare beneficiaries. Medicare Part D services are provided by privatized prescription drug plans (PDPs). The Centers for Medicare & Medicaid Services (CMS) are responsible for requirements and regulation.
- 1. Eligibility.** Although in practice MTMS encompasses a broad range of services that can benefit any patient, under Part D only patients who meet the following specific requirements are eligible for MTM:
    - a.** Multiple chronic conditions
    - b.** Multiple Part D medications
    - c.** Anticipated Part D medication costs of > \$4000 per year
  - 2.** CMS allows the PDPs to set their own criteria for what constitutes "multiple."
  - 3.** CMS allows the PDPs to determine how MTM will be or can be provided and includes the following:
    - a.** Patient mailings
    - b.** Call centers
    - c.** Pharmacist-provided MTM
  - 4.** Under Part D, when the provision of MTM is allowed by the PDP to be done by a patient's pharmacist, the PDP typically "pushes" the case to the pharmacy. MTMS provided to a Medicare patient prior to the "push" (i.e., a "pull" case) are typically not covered under Part D, and therefore payment by the PDP for services rendered may not occur.

## II. SCOPE OF MEDICATION THERAPY MANAGEMENT SERVICES

- A. Separation of MTM from dispensing**
- 1.** MTMS are provided by pharmacists in several settings. MTMS are distinctive and separate from dispensing services. Pharmacists may, at the time of dispensing, identify patients who would benefit from MTM. However, MTM is more in-depth than traditional medication counseling

mandated by Omnibus Budget Reconciliation Act of 1990 (OBRA '90). MTM is more holistic, generally encompassing the patient's entire medication regimen in the context of prevention, treatment, and management of conditions and disease states.

**B. Protection of patient information**

1. The provision of MTMS that includes patient interaction, documentation, and billing should ensure patient confidentiality and be compliant with the Health Insurance Portability & Accountability Act (HIPAA).

**C. Comprehensive versus focused MTMS**

1. A pharmacist can design his or her practice to provide several MTMS, including comprehensive medication therapy reviews (MTRs), specific disease state management programs, and/or targeted interventions. For example, a pharmacist may identify via the provision of a comprehensive MTR that his or her patient needs additional care for his or her diabetes (i.e., disease management) or perhaps needs strategies to improve adherence (i.e., targeted intervention).
2. Pharmacists providing disease state management services or targeted intervention programs can design their practice to include point-of-care laboratory assessment, cognitive services, product lines, and patient education. Examples of pharmacist-provided MTMS in various health care settings include but are not limited to the following:
  - a. Diabetes
  - b. Anticoagulation
  - c. Hypertension/hyperlipidemia
  - d. Adherence
3. Regardless of whether the service is comprehensive or focused, all MTMS involve patient interaction and participation to optimize therapeutic outcomes.

**D. Patients who may benefit from MTMS**

1. Complex pharmacotherapy patients
  - a. Multiple medications
  - b. Multiple disease states or conditions
  - c. Narrow therapeutic index medications
  - d. Medications requiring laboratory monitoring
2. High risk for loss of continuity of care
  - a. Multiple prescribers
  - b. Recent transitions of care (e.g., hospital discharge, rehabilitation, skilled nursing facility discharge)
3. Evidence of or high risk for medication nonadherence
  - a. Irregular refill history
  - b. History of failure to pick up new prescriptions
  - c. Stockpiling or incorrect pill counts
  - d. Financial burden (e.g., uninsured or underinsured)
  - e. Low health literacy
  - f. Poor transportation
  - g. Patient's beliefs indicate resistance to treatment
4. High-cost regimens
5. Noticeable decline in the patient's health or functionality

### III. ESSENTIAL COMPONENTS OF MEDICATION THERAPY MANAGEMENT

**A. Patient and pharmacist relationship**

1. Pharmacists have historically been viewed as one of the most trusted professionals based on Gallup's annual *Honesty and Ethics Survey*.<sup>4</sup> Pharmacists are also one of the most accessible health care professionals. Patients express greater satisfaction with care when they perceive quality interactions with a health care provider.
2. The provision of face-to-face MTMS strengthens the patient-pharmacist relationship. Although some MTMS can be provided via a phone interaction, face-to-face interaction with the pharmacist affords the ability for the pharmacist to observe visual signs and symptoms as well as changes in the patient's status and well-being.

3. For optimum patient care to occur, pharmacists need to be culturally competent and aware of the patient's level of health literacy.
  - a. Cultural competency means the pharmacists are cognizant of their patients' diversity regarding beliefs, values, behaviors, and language. Barriers in these areas can lead to miscommunication and poor health outcomes.
  - b. Health literacy is an individual's ability to obtain, understand, and follow directions related to his or her health care. According to the U.S. Department of Education, 9 out of 10 Americans have limitations regarding health literacy.<sup>5</sup> Patients with poor health literacy generally have poor health status and are more likely to have medication-related problems. The Rapid Estimate of Adult Literacy in Medicine–Revised (REALM-R) is a simple and quick tool that pharmacists can use to assess patient's health literacy.<sup>6</sup> Pharmacists need to adapt their counseling and MTMS based on the patient's health literacy level.
4. Successful MTM requires patient participation. Many MTM-related interventions require life-style or behavioral changes. Pharmacists need to assess their patients' willingness to participate and change. Pharmacists should know the stages of change delineated within the *Transtheoretical Model of Behavior Change* (Table 60-1).<sup>7</sup> Pharmacists can also use a 0-to-10 visual analog scale for assessing a patient's willingness to change. Scores  $\geq 5$  suggest the patient is willing to change and should be supported and encouraged.<sup>8</sup>

Table 60-1

EXAMPLE APPLICATION OF TRANSTHEORETICAL MODEL OF STAGES OF CHANGE<sup>7</sup>

Stage	Definition	Example Application (Self-Monitoring Glucose)
Precontemplation	Patient has no interest in changing behavior or sees no need to change	Patient discharged from hospital. Prescriptions for an oral antidiabetic agent and a glucose meter are called into pharmacy. Patient picks up oral agent but refuses the meter and states, "I'm not going to check my blood sugar. I'm not sticking myself. It's unnecessary. I don't have diabetes."
Contemplation	Patient is beginning to weigh pros and cons of change and is considering changing his or her behavior but is still somewhat ambivalent	Patient is discharged from hospital. Prescriptions for an oral antidiabetic agent and a glucose meter are called into pharmacy. Patient picks up oral agent and the glucose meter. She indicates at the time of purchase that she understands the importance of monitoring but refused a meter teaching session with the pharmacist. Three days later, the pharmacist calls to follow up with the patient and the patient states that she has not used the meter or taken it out of the box.
Preparation	Patient is taking action or shows signs of preparing to change	Patient is discharged from hospital. Prescriptions for an oral antidiabetic agent and a glucose meter are called into pharmacy. Patient pays for both and asks for the pharmacist to explain how to use the meter. She conducts her first finger-stick in the pharmacy and asks for a follow-up appointment to meet with the pharmacist to talk about diabetes and diet.
Action	Patient has implemented change(s)	Scenario is the same as in the aforementioned "Preparation," and when the pharmacist calls to check on the patient, she provides the pharmacist with values for twice daily blood glucoses. The pharmacist confirms the date for her follow-up appointment and tells her that she is doing a great job with monitoring and that her blood glucose values are getting better.
Maintenance	Patient is able to maintain positive changed behavior	Patient comes in monthly for medication refills, glucose strips, and lancets. Patient maintains a log of blood glucose values and has kept follow-up appointments with physician and pharmacist. Patient has started and adheres to a regular exercise routine and a low carbohydrate diet.

 RELAPSE  
& Bi-Directional Movement Between Stages Occurs

- B. Patient/caregiver interview.** Depending on the patient, it may be appropriate for the pharmacist to include a caregiver in the patient interview.
1. Interview setting
    - a. A semiprivate or private area is required for the provision of MTMS. For interviewing purposes, the more private the area, the fewer interruptions and the more likely the patient will share and retain pertinent information.
    - b. The interview area should have adequate lighting and a comfortable temperature. The space should be equipped with a table and chairs. The chair for patients should have arms to assist the patient in lowering to and rising from a seated position. The space should be large enough to accommodate the pharmacist, patient, and possible caregiver. In addition, the space should be readily accessible to patients with mobility problems (e.g., wheelchair, walker).
    - c. The space should be relatively quiet to facilitate conversation (e.g., ability to close a door to the space, no ringing phone). Many MTM patients are elderly and have hearing deficits. Failure to create an environment where background noise is minimized may escalate patient's frustration in communicating and adversely affect the desired outcomes.
  2. Essential technique
    - a. Use open and honest communication
      - (1) Introduce yourself.
      - (2) Explain the purpose and process of the MTM session.
      - (3) Ask for the patient's expectations, concerns, and/or issues to be addressed.
    - b. Avoid using and be aware of patients' incongruent body language (i.e., mismatch in verbal and nonverbal language).
    - c. Maintain good eye contact throughout the interview.
    - d. Conduct the patient interview at the patient level. Avoid medical jargon.
    - e. Ask purposeful questions.
    - f. Use a combination of open- and closed-ended questions. Open-ended questions cannot be answered with a simple yes or no and generally begin with who, what, when, or how.
    - g. Avoid rapid-fire questioning. Allow the patient time to answer a question before posing a second question.
    - h. Avoid leading questions, for example, "You take your cholesterol medicine at night, right?"
    - i. Use probing questions. Example: Questions asked to help elicit specific information from the patients regarding their medication therapy needs and problems.
    - j. Use nondefensive phrasing. For example, patients may become defensive with "why questions." Instead of asking "Why did you not take your blood sugar medicine?" ask "What caused you to not take your blood sugar medicine?"
    - k. Use active listening skills (*Table 60-2*).
    - l. Communication strategies for patients with disabilities. Patients with disabilities are capable of patient-centric care and should be empowered to be active participants.
      - (1) For patients with hearing deficits, remember to use a lower tone of voice and slower rate of speech. Use simpler sentences and sit directly across from the patient to facilitate lip-reading. Verbal education should be augmented with written materials. Consider providing and making available to your patient a sound amplifier.
      - (2) For patients with visual deficits (e.g., presbyopia, cataracts, glaucoma, macular degeneration, color blindness), clear and concise verbal communication becomes critical. When written communication or materials are necessary, these should be printed on nonglare, off-white, or pastel-colored paper. The font should be 14 points or greater in size; and avoid the use of yellow, green, and red.
      - (3) For patients with mental or cognitive deficits, the interview and education sessions may likely require the presence of a caregiver. Remember to always address the patient. Provide simple communication. Augment with simple written material.
  3. Essential components. The content gathered during a patient interview is essential to enable a comprehensive assessment. The outcome of MTMS depends on the quality of information and data that pharmacist has available. It takes a considerable amount of time to do a thorough patient interview as indicated by the following components.<sup>9</sup> To improve efficiency, the pharmacist may

**Table 60-2** USE OF ACTIVE LISTENING SKILLS IN THE PATIENT INTERVIEW

Active Listening Skill	Explanation	Application Example
Facilitation	The interviewer uses words, body language, and/or posture to encourage the patient to continue.	Patient: "I just haven't been feeling well lately." Pharmacist: [while maintaining eye contact and leaning in toward the patient] "Tell me more."
Interpretation	The interviewer deduces there is a problem based on a statement or statements and asked the patient to address the finding.	Pharmacist: "I noticed that you have asked some questions about memory today. Do you have concerns about your memory?"
Reflection	The interviewer checks his or her understanding of what the patient has said by repeating back a statement or statements in the patient's words and gauges the patient's response.	Patient: "... and my doctor told me to start taking ½ tablet for my cholesterol." Pharmacist: "Your doctor told you to take a ½ tablet?" Patient: "Yes"
Clarification	The interviewer asks for more detail when he or she does not fully understand what the patient has said or implied.	Pharmacist: "You said you only take your naproxen when you need it. How often do you have to take it?" Patient: "Not often." Pharmacist: "How many times a week do you have to take it?"
Empathy	The interviewer recognizes the patient's feelings.	Patient: "I was in so much pain. I thought I was going to die." Pharmacist: "That must have been very difficult and scary for you. How is your pain today?"
Confrontation	The interviewer uses an observation, a patient behavior, or an aspect of the interview to engage the patient in addressing a problem or situation.	Situation: The patient's self-monitored blood glucose values have been consistently high. Pharmacist notices in the patient's shopping cart several food items that are high in sugar/carbohydrate. Pharmacist: [begins confronting the patient with] "Have you ever had any diet education for your diabetes?"
Silence	Silence can be used in two ways: (1) remaining silent after posing a question to enable the patient time to gather his or her thoughts and answer, and (2) remaining silent after a patient's statement can at times be used to prompt the patient to share more detail.	Patient: "My daughter took me to the emergency room last month." Pharmacist: [maintains eye contact and remains silent, encouraging the patient to continue] Patient: "They admitted me for pneumonia."

have the patient complete or provide information in advance or train a technician to assist with data collection.

- a. Basic patient demographics (e.g., name, date of birth, address)
- b. Chief complaint or reason for evaluation. In addition, it is helpful to ascertain what the patient/caregiver wishes to accomplish by the MTMS. In other words, what are the patient/caregiver's expectations?
- c. Health care priority. Comfort, cost, or convenience
- d. Past medical history, including surgeries and procedures, as well as any recent hospitalizations or emergency department visits
- e. Preventative health information such as immunizations and health screenings (e.g., colonoscopy, Pap smear, mammogram, prostate examination)

- f. Family history
  - g. Social history that includes caffeine, nicotine, alcohol, prescription or illicit drug abuse, exercise, diet, occupation, and support network
  - h. Allergies
  - i. Medication history. Prescription, over-the-counter, herbal, and home remedies
    - (1) Medication name and strength
    - (2) Dose and directions (as labeled vs. how taken)
      - (a) For as-needed medications (PRN). Frequency of use and when last dose occurred
    - (3) Indication
    - (4) Duration
    - (5) Perceived efficacy and side effects. If there are reported problems with efficacy or side effects, it may be helpful to inquire about other medications that have been previously tried and failed.
    - (6) Prescriber
    - (7) Pharmacy that filled the medication if not filled by interviewing pharmacist/pharmacy
    - (8) Date last refilled (consider a pill count to help with measuring adherence)
    - (9) Recent changes. Medications added or discontinued and/or dosage changes
  - j. Vitals and lab values
    - (1) Review of the patient's medication list prior to the appointment may be helpful to pinpoint and request the patient bring certain lab values to his or her appointment, or
    - (2) Consider having the patient sign a medical release during the appointment to enable the pharmacist to obtain lab values from the patient's physician.
  - k. Review of systems. The pharmacist may be the first professional to detect a health problem for which a referral may be necessary. In addition, a generalized review of systems reveals problems or conditions not commonly reported in a medical history such as falls, incontinence, and constipation. A review of systems may detect side effects that the patient did not realize may be associated with his or her medications (e.g., dry mouth).
  - l. Contact information for all prescribers and insurance information (e.g., Medicare Part D PDP)
- C. Medication therapy review (MTR).** The MTR is conducted to determine appropriateness of therapy. The pharmacist should concentrate on necessity, safety, and efficacy of therapy. A useful outcome of the MTR is the detection/creation of a problem list (i.e., medication-related problems).
- 1. Basic components of an MTR can be found within the medication appropriateness index,<sup>10</sup> which helps to provide a systematic approach to the MTR.
    - a. Is there a justification/indication for the medication?
    - b. Is there any allergy or contraindication for the medication?
    - c. Is the medication or regimen being used the most efficacious?
    - d. Is the dose (age/condition) appropriate?
    - e. Are the directions optimized?
    - f. Are necessary monitoring parameters/practices in place?
    - g. Is the duration of use appropriate?
    - h. Are there any therapeutic duplications?
    - i. Are there any drug–drug interactions? Drug–food? Drug–disease?
    - j. Are there more cost-effective therapies available?
    - k. Is the patient adherent with therapy?
    - l. Are there any untreated conditions?
- D. Therapeutic planning.** The problem list created from your systematic MTR is used to create a therapeutic plan.
- 1. The plan should be patient-centric, and with MTM for Medicare Part D, the plan is referred to as the Medication Action Plan.
  - 2. The therapeutic plan is designed to prevent, alleviate, and eliminate medication-related problems.
  - 3. The plan should be written to serve as documentation for services provided.
  - 4. Pharmacists may choose to use a traditional SOAP or FARM format for their documentation (*Table 60-3*).
  - 5. Ideally, therapeutic plans should include the following:
    - a. Goals for therapy
    - b. The patient's status on desired outcomes

**Table 60-3** COMPONENTS OF A FARM AND SOAP NOTE

FARM Note	SOAP Note
Findings (F)	Subjective data (S) and Objective data (O)
Assessment (A)	
Resolution/Recommendation (R)	Plan (P)
Monitoring (M) and follow-up	

- c. Recommendations for intervention
  - d. Recommended monitoring parameters
  - e. Desired time frame for follow-up
  - f. Contingency plans for treatment may also be included in the event that treatment goals are not reached.
6. Without appropriate follow-up, even the best of therapeutic plans are likely to fail. The success of therapeutic plans also depends on patient adherence, which is why this process should be patient-centric.
  7. The therapeutic plan required for Medicare Part D beneficiaries (i.e., MAP) should be developed in collaboration with the patient and should contain action items for which the patient is responsible.
- E. Patient Medication Record (PMR).** After a comprehensive MTM, patients should be provided with PMR containing list of all of their medications, doses, directions, indications, any precautions, and start/stop dates. The patients should be instructed to present their PMR to all health care providers. The pharmacist should assist the patients in updating their PMR regularly and upon changes to the patient's regimen.
- F. Documentation** is an essential function of the MTM process. The age-old adage "if it's not documented, then it wasn't done" remains true.
1. Pharmacist should maintain MTM files for their patients that include their interview notes, medication therapy review workup, the therapeutic plan, and follow-up care. In addition, separate paperwork may be needed and should be maintained for billing.
  2. Since 2006, both pharmacies and pharmacists must have a national provider identifier number (NPI#) to bill for clinical services. Pharmacists can obtain their NPI# from the National Plan & Provider Enumeration System at <https://nppes.cms.hhs.gov/NPPES/Welcome.do>.
  3. Current procedural technology (CPT) codes are commonly used for billing by health care professionals for patient care. There are three CPT codes for MTMS (*Table 60-4*).<sup>11</sup> These HIPAA-compliant codes may be used when billing third-party payers for services; however, the billing codes

**Table 60-4** CURRENT PROCEDURAL TECHNOLOGY (CPT) CODES FOR MEDICATION THERAPY MANAGEMENT (MTM)<sup>11</sup>

Definition of CPT Codes	
<b>99605</b>	MTM service(s) provided by pharmacist, individual, face-to-face with patient, initial 15 mins, with assessment, and intervention if provided; initial 15 mins, new patient
<b>99606</b>	Initial 15 mins, established patient
<b>99607</b>	Each additional 15 mins (list separately in addition to code for the primary service). (Use 99607 in conjunction with 99605 and 99606.)

**Table 60-5****MEDICARE PART D FIVE CORE COMPONENTS OF MEDICATION THERAPY MANAGEMENT<sup>12</sup>****MTM Core Components**

---

Medication therapy review (MTR)  
 Personal medication record (PMR)  
 Medication action plan (MAP)  
 Intervention and referral  
 Documentation and follow-up

---

do not guarantee coverage, and hence payment, for services rendered. Therefore, patients need to be informed of the fees for MTMS prior to the provision of care.

4. For Medicare Part D, the MMA and CMS mandate that MTM be provided for eligible beneficiaries, but the decision for how MTM will be provided is left to the PDPs. Some Medicare Part D PDPs have contracted with specific MTM online services, such as Mirixa and Outcomes Pharmaceutical Health Care. Pharmacists conducting MTM for beneficiaries of these PDPs must complete training on how to document and bill with these specific platforms.
- G. Medicare Part D core components for MTMS.** Pharmacists may offer many services within the framework of the essential components noted earlier. MTM through Medicare Part D requires five core components (*Table 60-5*).<sup>12</sup>

## Study Questions

Choose the best answer for questions 1-5.

- In the provision and billing of MTM services for a Medicare Part D patient, the pharmacist must complete:
  - a comprehensive medication review.
  - a personal medication record.
  - a medication action plan.
  - I only
  - III only
  - I and II only
  - II and III only
  - I, II, and III
- Mrs. Smith has recently been diagnosed with hypertension and hypercholesterolemia. She presents to your pharmacy today with new prescriptions for hydrochlorothiazide and simvastatin. When she picks up her medications, she asks to speak with the pharmacist. She asks several questions about her new regimen and inquires about how she can check her own blood pressure. According to the transtheoretical model for behavioral change, what stage is Mrs. Smith?
  - Precontemplation
  - Contemplation
  - Preparation
  - Action
  - Maintenance
- Which of the following are forms of active listening interview techniques?
  - Restoration
  - Facilitation
  - Silence
  - I only
  - I and II only
  - I and III only
  - II and III only
  - I, II, and III
- The documentation of your recommendation for the patient to have a follow-up A1c obtained in 3 months should be noted in which section of a SOAP note?
  - Subjective
  - Objective
  - Observations
  - Assessment
  - Plan
- Pharmacists who bill Medicare for MTM services must have a:
  - pharmacist license.
  - national provider identifier number.
  - medication appropriateness index number.
  - I only
  - I and II only
  - I and III only
  - II and III only
  - I, II, and III only

## Answers and Explanations

1. **The answer is E** [see III.G; Table 60-5].

The provision of MTM for Medicare Part D must include the five core components of MTM. A comprehensive medication review, personal medication record for the patient, and a patient-centric medication action plan represent three of the five core components. The remaining two are intervention and referral and documentation and follow-up.

2. **The answer is C** [see III.A.4; Table 60-1].

The patient is preparing to take action toward changing her personal care of her hypertension and hypercholesterolemia by seeking medical attention, picking up her new prescriptions, asking for information from the pharmacist, and showing interest in wanting to learn to self-monitor. This is the stage preparation instead of action because the patient has not yet implemented the changes in her personal care.

**3. The answer is D** [see III.B.2.k; Table 60-2].

Facilitation and silence are well-recognized methods of utilizing active listening within a patient interview. Restoration is not one of the active listening skills. The remaining active listening skills are interpretation, reflection, clarification, empathy, and confrontation.

**4. The answer is E** [see III.D.4; Table 60-3].

When using a SOAP format for documentation, all recommendations, including follow-up lab work, should be noted in the plan (P) section of the SOAP note. The sections of a SOAP note are subjective, objective, assessment, and plan. Observation is not a section.

**5. The answer is B** [see III.F.2].

Since 2006 under the Medicare Modernization Act of 2003, licensed pharmacists can bill for MTMS provided to patients. Pharmacists need a national provider identifier number (NPI#).

# Adverse Drug Reaction Reporting

BARBARA SZYMUSIAK-MUTNICK

**I. INTRODUCTION.** The Institute of Medicine reported in July 2006 that an estimated 1.5 million injuries occur each year as a result of medication errors and between 44,000 and 98,000 people die from medication errors annually. Other studies estimate as many as 225,000 deaths occur annually from medication errors, which makes it the third leading cause of death in the United States following heart disease and cancer. The cost of morbidity and mortality owing to drug-related adverse events in hospitalized patients was recently estimated to be at least \$3.5 billion annually. There are an estimated 3 million hospital admissions each year caused by the misuse of pharmaceuticals. The suffering that patients experience because of drug-related events cannot be quantified.

Adverse drug reactions (ADRs) are a cause of significant morbidity and mortality in patients in all areas of health care today. There is wide variation in the current health care literature, but it has been estimated that from one-third to as high as one-half of ADRs are believed to be preventable.

**II. DEFINITIONS.** The terms *adverse drug reaction*, *adverse drug event*, *untoward drug reaction*, *drug misadventure*, *side effect*, *medication errors*, *misuse of pharmaceuticals*, and *drug-related problem* are many times used interchangeably but do not always describe the same situation.

- A. The National Coordinating Council for Medication Error Reporting and Prevention states “A medication error is any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of the health care professionals, patient, or consumer. Such events may be related to professional practice, health care products, procedures, and systems, including prescribing; order communication; product labeling, packaging, and nomenclature; compounding; dispensing; distribution; administration; education; monitoring; and use.”<sup>1</sup>
- B. The U.S. Food and Drug Administration’s (FDA) definition of an **adverse event** is “Any untoward medical occurrence in a patient or clinical investigation subject administered a pharmaceutical product and which does not have to have a casual relationship with this treatment.”<sup>2</sup>
- C. **Adverse drug reaction** is defined by the World Health Organization (WHO) as “one which is noxious and unintended, and which occurs at doses normally used in man for the prophylaxis, diagnosis, or therapy of disease, or for the modification of physiological function.”<sup>3</sup>

## III. TYPES OF ADVERSE DRUG REACTIONS

### A. Type A

1. Type A reactions are extensions of the drug’s known pharmacology and are responsible for the majority of ADRs.

<sup>1</sup><http://www.nccmerp.org/aboutMedErrors.html>

<sup>2</sup><http://www.fda.gov/downloads/Drugs/GuidanceComplianceRegulatoryInformation/Guidance/UCM073087.pdf>

<sup>3</sup><http://www.who.int/mediacentre/factsheets/fs293/en/>

2. Type A reactions are usually dose dependent and predictable but can be the result of concomitant disease states, drug–drug interactions, or drug–food interactions.
  3. Ways to minimize type A reactions include understanding the pharmacology of the drug being prescribed, monitoring drugs with a narrow therapeutic index, and avoiding polypharmacy when possible.
- B. Type B**
1. Type B reactions include idiosyncratic reactions, immunological or allergic reactions, and carcinogenic/teratogenic reactions.
  2. Type B reactions are usually not the result of a known pharmacology of the drug but seem to be a function of patient susceptibility. They are rarely predictable, are usually not dose dependent, and seem to concentrate in certain body systems such as the liver, blood, skin, kidney, and nervous system.
  3. Type B reactions are uncommon but are generally serious and can be life threatening.
  4. Except for immediate hypersensitivity reactions, type B reactions may take as long as 5 days before the patient demonstrates hypersensitivity to a drug. There is no maximum time for the occurrence of a reaction, but most occur within 12 weeks of initiation of therapy.

#### IV. RECOGNITION

- A.** Drugs must always be considered as a possible cause of disease or symptoms that are among a patient's list of complaints. Complete drug histories, including nonprescription drugs, must be carried out.
- B.** Recognition is often subjective, and it is not always possible to demonstrate strong causality between the drug and the occurrence.
1. Several factors may help in assessing the determination of causality.
    - a. Did the patient actually ingest the drug in question?
    - b. Did the onset of symptoms occur after the drug was taken?
    - c. What is the time interval between taking the drug and the onset of symptoms?
    - d. Did the symptoms resolve or improve after the drug was stopped or the dose decreased?
    - e. Did the symptoms reoccur after the drug was reintroduced?
    - f. Did drug–drug interactions contribute to the symptoms?
    - g. Were the drugs measured in “toxic levels” in the patient's serum?
    - h. Has this reaction been previously seen with use of the drug?
    - i. What is the personal experience of the clinician with previous use of the drug and reactions secondary to the drug?
  2. Nomograms have been developed to aid in the assessment of causality.

**V. SURVEILLANCE PROGRAMS.** Pharmacists as well as all health care professionals should take an active role in monitoring, reporting, and trending ADR information. Some of the activities involved in a concurrent and ongoing ADR surveillance program at an institutional level include the following components:

- A.** Pharmacy departments should take the lead in the collection of information and should submit all reviews and reports to the pharmacy and therapeutics committees for review and evaluation.
1. Encourage all health care professionals to be involved in reporting.
  2. Monitor patients who are using high-risk agents.
  3. Review patients who have received “antidote”-type drugs.
  4. Notify prescribers of suspected ADRs, and encourage thorough documentation of the description of the reaction as well as the outcome in patients' medical records.
  5. Report appropriately identified ADRs to the FDA.
  6. Develop the use of pharmacy computer systems to track ADRs.
- B.** Evaluation of the causes of ADRs should be carried out. ADR report information should be used for educational purposes and identification of drug use and medication use processes to prevent further occurrences of such reactions. ADR reporting information should be incorporated into institutional risk management programs.

**VI. REPORTING TO THE FDA.** Three of the five major centers at the FDA are involved with evaluating the safety and efficacy of drugs. The largest center is the Center for Drug Evaluation and Research (CDER), which oversees both prescription and nonprescription/over-the-counter (OTC) drugs. In 2002, CDER established the Adverse Events Reporting System (AERS), a computerized database designed to support the FDA's postmarketing safety program for drugs and therapeutic biologic products. Annually, the AERS receives about 500,000 reports of adverse experiences possibly associated with drugs. The Center for Biological Evaluation and Research (CBER) ensures the safety and efficacy of blood products, vaccines, allergenics, biological therapeutics, gene therapy, medical devices and tests, xenotransplantation products, and banked human tissue and cellular products. The Center for Food Safety and Applied Nutrition (CFSAN) established the CFSAN Adverse Events Reporting System (CAERS) in 2002. The CAERS provides a monitoring system to identify potentially serious problems secondary to non-FDA-approved herbs, minerals, vitamins, dietary supplements, and other substances.

- A.** The national **Vaccine Adverse Event Reporting System (VAERS)** is coadministered by the FDA and the Centers for Disease Control and Prevention (CDC). More than 10 million vaccines are given to children who are younger than 1 year of age and many million more doses to adults each year. Although vaccines protect many people from dangerous diseases, they do have the potential to cause adverse effects. Approximately 15% of events reported to the VAERS are considered "more serious" and include those that require hospitalization, are life-threatening events, and cause death.
1. The National Childhood Vaccine Injury Act (NCVIA) requires health professionals to report
    - a. Adverse events after the administration of vaccines specified in the act, as described in the "Reportable Events Table," within the specified period (available at <http://www.vaers.hhs.gov/reportable.htm> or 1-800-822-7967)
    - b. Any event listed in the manufacturer's package insert as a contraindication to subsequent doses of the vaccine
  2. In 1990, VAERS was set up to receive all reports of suspected adverse events caused by any U.S. licensed vaccine. Information on reporting online, by fax, or mail can be viewed at <http://vaers.hhs.gov/esub/index>.
  3. The VAERS depends on voluntary reporting by health professionals to
    - a. Identify rare adverse reactions not detected in prelicensing studies
    - b. Monitor for increases in already known reactions
    - c. Identify risk factors or preexisting conditions that promote reactions
    - d. Identify particular vaccine lots with unusually high rates or unusual types of events
- B. MedWatch**, the FDA's Safety Information and Adverse Event Reporting Program established in 1993, is a voluntary system for health care providers using Form FDA 3500, which is available at <http://www.accessdata.fda.gov/scripts/medwatch/>. However, manufacturers and distributors of FDA-approved drugs, biologics, radiation-emitting devices, special nutritional products, dietary supplements, infant formulas, and devices are mandated to report problems to the FDA. The goals of the program are to increase awareness of reporting of medical-product-induced diseases and the importance of reporting, to clarify what should be reported, to make reporting as easy as possible, and to provide feedback to health professionals.
1. **Importance of reporting**
    - a. The incidence of ADRs occurs at a high rate in health care today.
      - (1) Generally, it is reported that 3% to 11% of all hospital admissions can be attributable to ADRs, although some studies report the figure to be as high as 29%.
      - (2) The likelihood that a patient will experience an ADR while hospitalized is reported in the literature to be in a range from 5% to 25%.
    - b. Prevention of ADRs is an important strategy in health care. It has been further noted that preventable ADRs tend to be the most costly to treat and cause the greatest degree of patient morbidity.
      - (1) Future ADRs can be prevented in individual patients by careful and consistent documentation in patient records.
      - (2) A program that tracks ADRs can help discover previously unidentified trends. These trends can be used within the institution to develop programs of prospective intervention to prevent reoccurrence of the reaction in the patient populations that are at similar risk.

- c. Recognition of previously undiscovered ADRs attributable to a drug is particularly true in the case of newly marketed products.
    - (1) Although clinical trials are generally effective in assessing efficacy and risk to benefit ratio, inherent limitations exist in premarketing trials.
      - (a) The trials are usually relatively short in duration and do not effectively mimic the exposure patients would experience if using the drug as a chronically administered agent.
      - (b) Drug–drug interactions and use in patients with concomitant disease states may not be tested for in these trials.
      - (c) The small size of the trials may be insufficient to detect rarely occurring adverse reactions.
      - (d) Age, racial, and ethnic groups may not be participating in the same numbers as represented in the general population.
    - d. Prompt recall in cases of product problems are accomplished when the MedWatch Program is used to report product problems or device defects.
  - 2. **What should be reported?**
    - a. ADRs that are serious, even if causality is not proven, including
      - (1) A patient’s death that is suspected of being a direct outcome of an ADR
      - (2) A life-threatening event
      - (3) An initial or prolonged hospitalization
      - (4) A significant, persistent, or permanent change or disability/incapacity
      - (5) A congenital anomaly (including those occurring in a fetus)
      - (6) Other problems that are not listed in the manufacturer’s package insert as a known side effect, especially those that may jeopardize the patient and require medical or surgical intervention.
    - b. Product problems that can result in compromised safety or quality, including product contamination, mislabeling, unclear labeling, poor packaging, potency problems, and questionable stability
    - c. Counterfeit or suspected counterfeit drugs
    - d. Adverse events owing to blood products, allergenics, gene therapy, human tissue and cellular products, and xenotransplantation products
    - e. Medication errors
    - f. Adverse events with food, herbs, vitamins, cosmetics, or dietary supplements, although CAERS is the preferred reporting system
    - g. Malfunctioning medical devices such as heart valves, latex gloves, dialysis machines, and ventilators and problems with nutritional products or use of a medical product that required surgical or medical intervention to prevent permanent damage to a body function or structure
  - 3. **Confidentiality** of both the reporter and the patients whose cases are reported are substantially protected by the FDA. The Health Insurance Portability and Accountability Act (HIPAA) Privacy Rule is not intended to disrupt or discourage ADR reporting in any way. The rule specifically permits covered entities, such as pharmacists, physicians, or hospital representatives, to report adverse and other quality-related events. Accordingly, the HIPAA Privacy Rule permits covered entities to disclose protected health information without authorization for specified public health purposes.
  - 4. Reporting of problems with OTC medications are required when the product has been marketed with a new drug application (NDA), including drugs formerly marketed as prescription-only drugs. OTC products marketed without an NDA do not require reporting, but reporting is strongly encouraged. Approval of the FDA is not required for the marketing of nonprescription herbs, minerals, vitamins, dietary supplements, and other substances. Because the FDA does not approve these substances, efficacy and safety do not have to be demonstrated, nor is it mandated to report problems to the FDA.
  - 5. Reporting to manufacturers is not described in the FDA’s guidelines, although a section of the MedWatch form can be checked off to inform the FDA that a copy of the report has been forwarded to the manufacturer by the reporter.
- C. Information on previously reported events can be found on the FDA Web site that provides online safety information at <http://www.fda.gov/medwatch/safety.htm>.

**VII. AMERICAN SOCIETY OF HEALTH-SYSTEMS PHARMACISTS (ASHP) GUIDELINES.** ASHP encourage reporting of serious or unexpected ADRs to the FDA, the manufacturer, or both.

**VIII. THE JOINT COMMISSION.** The Joint Commission requirements for accreditation describe the need for each health care organization to monitor for adverse events involving drugs and devices in a continual, collaborative fashion.

**IX. UNITED STATES PHARMACOPEIA (USP).** MEDMARX and the Medication Errors Reporting Program at the USP Institute for Safe Medication Practices (ISMP) Medication Errors Reporting Program is now reported to Quantros MEDMARX at <http://www.quantros.com/medmarx.htm>.  
For MER information, contact ISMP at <http://www.ismp.org> or 1-800-324-5723.

## X. FURTHER INFORMATION

- A. Information about the MedWatch program can be obtained by phone at 1-800-FDA-1088 and at <http://www.fda.gov/Medwatch/>.
- B. Information about VAERS can be obtained by phone at 1-800-822-7967 and at <http://www.fda.gov/cber/vaers/vaers.htm>.
- C. Information about reporting to the CFSAN program can be obtained by phone at (1-888-SAFE-FOOD) or at <http://www.cfsan.fda.gov>.
- D. Further information about the FDA's reporting systems and programs, such as CDER, can be found on the FDA's Web site (<http://www.fda.gov>).

## Study Questions

**Directions:** Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. The phrase "one which is noxious and unintended, and which occurs at doses normally used in man for the prophylaxis, diagnosis, or therapy of disease, or for the modification of physiological function," describes
  - (A) a side effect.
  - (B) an adverse drug reaction.
  - (C) an adverse drug event.
  - (D) a medication error.
  - (E) prescribing error.
2. Type A reactions are characterized by which of the following?
  - (A) Idiosyncratic reactions
  - (B) A function of patient susceptibility
  - (C) Caused by drug-drug interactions
  - (D) Permanent medical complication
  - (E) Death
3. The MedWatch form is *not* the appropriate form to report which of the following events?
  - (A) A vaccine event described in the Vaccine Adverse Event Reporting System (VAERS) "Reportable Events Table"
  - (B) A suspected counterfeit drug
  - (C) A malfunctioning ventilator
  - (D) A drug that is contained in a package with unclear labeling
  - (E) An adverse reaction resulting in patient death
4. Type B adverse drug reactions are
  - (A) generally serious and can be life threatening.
  - (B) a result of the known pharmacology of the drug.
  - (C) usually predictable.
  - (D) responsible for the majority of ADRs.
  - (E) usually dose dependent.

5. HIPPA rules require the following before reports are submitted to the FDA.
- (A) Written permission of the patient
  - (B) Written permission of the patient's attending physician
  - (C) Written permission of the patient and the patient's attending physician
  - (D) Written permission from the medical records department
  - (E) Reports can be submitted without authorization of the patient or health care providers
6. Reasons for close scrutiny of previously unreported ADRs in newly marketed drugs are based on all of the following concerns except:
- (A) Premarketing clinical trials may have a small number of subjects.
  - (B) Groups based on age, race, and ethnicity may not be represented in the same proportion in study groups as in the general population.
  - (C) ADRs that have been reported in premarketing trials are not included as part of the FDA surveillance of events in the voluntary reporting system.
  - (D) Trials are relatively short in duration.
  - (E) Trials may not effectively test medications that will be chronically administered agents.

## Answers and Explanations

---

1. **The answer is B** [see II.C].  
This is the definition from the WHO.
2. **The answer is C** [see III.A.2].  
Type A reactions can be caused by drug–drug interactions. Idiosyncratic reactions and reactions caused by patient susceptibility are generally in the classification of type B reactions.
3. **The answer is A** [see VI.A.1].  
All the others are reportable on the MedWatch form. The National Childhood Vaccine Injury Act requires the use of a VAERS form to report vaccine-related injuries.
4. **The answer is A** [see III.A; III.B].  
The other answers describe type A reactions.
5. **The answer is E** [see VI.B.3].  
The Health Insurance Portability and Accountability Act (HIPAA) Rule permits covered entities to disclose protected health information without authorization for specified public health purposes.
6. **The correct answer is C** [see VI.B.c.1].

# Medication Errors

ROBERT CISNEROS

## I. MEDICATION ERROR PROBLEM

- A. The 2000 Institute of Medicine (IOM) report *To Err Is Human* brought the problem of errors in medicine to national attention.<sup>1</sup>
  1. An estimated 44,000 to 98,000 **deaths per year** are caused by medical errors. **Of those deaths**, approximately 7000 are the result of medication errors.
  2. A call to action was given to improve patient safety.
- B. In recent years, tragic medication errors have focused attention on concerns regarding patient safety.
  1. A chemotherapy mix-up at a major cancer center resulted in the death of a patient from a **four-fold overdose** daily for 4 days.
  2. A child accidentally received an **intravenous rather than intramuscular** dose of long-acting penicillin and died.
  3. A compounding error resulted in death of a child who received a tricyclic antidepressant at a dose **10 times greater than the dose prescribed** by physician.
  4. Mix-ups with heparin vials that had **similar packaging, but different concentrations**, resulted in **overdoses** causing serious injury and several infant deaths.

**II. ERROR DEFINITION.** The National Coordinating Council for Medication Error Reporting and Prevention (NCCMERP) defines a medication error as follows: “A medication error is any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of the health care professional, patient, or consumer. Such events may be related to professional practice, health care products, procedures, and systems, including prescribing; order communication; product labeling, packaging, and nomenclature; compounding; dispensing; distribution; administration; education; monitoring; and use.”<sup>2</sup>

**III. TYPES OF ERRORS.** The following categories of errors have been used in numerous research studies.<sup>3</sup>

- A. **Wrong drug error.** A drug that was not ordered for a patient was administered—for example, a patient accidentally received furosemide 40 mg orally. Possible causes: The pharmacist accidentally filled the patient’s prescription for an antibiotic with furosemide; the pharmacist reached for the wrong bottle on the shelf and did not check the label carefully enough.
- B. **Extra dose error.** A patient receives more doses of a drug than were ordered—for example, a patient was supposed to receive a medication with breakfast for 3 days but received it for 5 days. Possible cause: The patient’s nurse was confused by the medication directions.
- C. **Omission error.** A dose of a drug was not administered as ordered but was skipped—for example, a patient was supposed to receive digoxin 0.25 mg orally in the morning but did not receive the dose. Possible cause: The patient’s nurse was so busy that he or she forgot to administer the dose.

<sup>1</sup>Kohn LT, Corrigan JM, Donaldson MDS, et al., eds. *To Err Is Human: Building a Safer Health System*. Washington, DC: National Academy Press; 2000.

<sup>2</sup>NCCMERP, “What Is a Medication Error,” available at <http://www.nccmerp.org/aboutMedErrors.html>.

<sup>3</sup>Cohen MR, ed. *Medication Errors*. Washington, DC: American Pharmaceutical Association; 1999.

- D. **Wrong dose or wrong strength error.** Either the wrong dose of a medicine or the wrong strength is administered—for example, the patient was supposed to receive warfarin 0.5 mg but received warfarin 5 mg instead. Possible causes: The pharmacist misread the label; the physician wrote the order as “warfarin .5 mg.” Another example: A patient was supposed to receive timolol 0.25% but was given timolol 0.5%. Possible cause: The pharmacist took the wrong product off the shelf, confused by the concentrations.
- E. **Wrong route error.** A patient receives a dose of a medication by a route that was not ordered by the physician—for example, a patient was supposed to receive prochlorperazine 10 mg intramuscularly but the drug was administered intravenously. Possible causes: The nurse misread the orders; the physician mistakenly wrote “IV” instead of “IM.”
- F. **Wrong time error.** A patient does not receive a dose of medication at the time at which it was to be administered—for example, a hospitalized patient with diabetes is scheduled to receive a dose of insulin immediately before breakfast (at 7:00 A.M.), but the dose is given 2 hrs after breakfast. Possible cause: The nurse was busy and could not give dose on time.
- G. **Wrong dosage form error.** A patient receives a dose of medicine in a dosage form that was not intended—for example, nicotinic acid 500 mg tablets were ordered for a patient who instead receives nicotinic acid 500 mg slow-release capsules. Possible cause: The pharmacist did not carefully check the product or was confused by the label.
- H. **Other.** Errors that do not fit into any of the other categories.

#### IV. COMMON ERROR HAZARDS

- A. **Dangerous abbreviations.** Numerous common abbreviations and symbols have been associated with errors. Detailed lists are available from the Institute for Safe Medication Practices (ISMP) at <http://www.ismp.org/tools/errorproneabbreviations.pdf> and The Joint Commission at [http://www.jointcommission.org/assets/1/18/official\\_do\\_not\\_use\\_list\\_6\\_111.pdf](http://www.jointcommission.org/assets/1/18/official_do_not_use_list_6_111.pdf). JCAHO’s accredited organizations are required to avoid using the potentially confusing abbreviations on its “do not use” list.
  - 1. **U, IU: unit(s).** The letter *U* can easily be misinterpreted as a number (e.g., 0 or 4), and serious harm has occurred with insulin and heparin as a result of this confusion. For example, a patient received 66 units of insulin instead of 6 units. The order, which was written for “6U” of regular insulin, was misread as 66. The word *units* should be written out in full.
  - 2. **QD, Q.D., qd, q.d. (daily).** These common abbreviations have been misinterpreted as “QID” or “qid” (four times daily) resulting in overdoses. The word *daily* should be written out in full.
  - 3. **Q.O.D, QOD, qod (every other day).** These common abbreviations have been misinterpreted as QID (four times daily), resulting in overdoses. The words *every other day* should be written out completely.
  - 4. **Trailing zero.** When a dose is ordered and followed with a decimal point and a zero, such as 2.0 mg or 25.0 mg, errors can occur. The decimal point may be missed and an overdose can occur. For example, warfarin 2.0 mg may be misinterpreted as 20 mg. Trailing zeros should be avoided, and the dose written without the additional zero—for example, warfarin 2 mg (instead of 2.0 mg).
  - 5. **Lack of leading zero.** A drug’s dose may be less than 1 mg, such as for digoxin. Often the dose is written without a leading zero: digoxin .25 mg instead of digoxin 0.25 mg. Errors have occurred because the decimal point is missed—for example, warfarin .5 mg may be interpreted as warfarin 5 mg. Leading zeroes should be included, so the dose is written as digoxin 0.25 mg or warfarin 0.5mg.
  - 6. **MS, MSO<sub>4</sub> (morphine sulfate), MgSO<sub>4</sub> (magnesium sulfate).** The abbreviations for morphine sulfate and magnesium sulfate are quite similar and can be confused. It is recommended that *morphine sulfate* and *magnesium sulfate* be written out in full.
- B. **Other confusing symbols and abbreviations.** There are numerous other hazardous symbols and abbreviations that should be used with caution when writing prescription orders and carefully examined when filling prescriptions. Examples include the following:
  - 1. **cc.** Stands for cubic centimeters and is often used instead of mL. This has been misinterpreted as a 0 (zero); use mL.
  - 2. **μg.** Used for micrograms—for example, levothyroxine 250 μg daily. The abbreviation has been mistaken for mg, and overdoses have occurred; better to use mcg or to write out the word *micrograms*.
  - 3. **<, >.** Symbols for less than (<) and greater than (>) have been mistaken for each other or misinterpreted as numbers. Better to write out the words *less than* or *greater than*.

4. **HCT.** This abbreviation for “hydrocortisone” has been misinterpreted as hydrochlorothiazide. Better to write out the word completely.
  5. **HCl.** The abbreviation for “hydrochloric acid” has been misinterpreted as KCl (potassium chloride). Better to write out the words completely.
- C. **Sound-a-like or look-a-like drug names.** The ISMP has a list of confusing drug names available at <http://www.ismp.org/Tools/confuseddrugnames.pdf>.
1. Examples include the following:
    - a. Amitriptyline and aminophylline
    - b. Cisplatin and carboplatin
    - c. K-Dur and Cardura
  2. To avoid these problems, the ISMP offers several suggestions, including the use of computerized reminders, name alert stickers, and independent checks; opening the bottle in front of the patient, who can confirm the appearance; and reporting errors.
- D. **High-risk drugs.** Certain **potent drugs** have been implicated in many serious and tragic medication errors. These have been called high-risk or high-alert drugs. A list of such medications can be found at <http://www.ismp.org/Tools/highalertmedications.pdf>. Examples include the following:
1. **Blood-modifying agents such as heparin and warfarin.** Errors have resulted in serious injury or death from hemorrhaging as a result of overdose (patient receiving 10 mg instead of 1 mg) or from blood clots as a result of underdose (patient receiving 0.5 mg instead of 5 mg).
  2. **Narcotics and sedatives.** Central nervous system depression and respiratory arrest have resulted from errors with these drugs, such as diazepam 25 mg given intravenously instead of 2.5 mg.
  3. **Neuromuscular paralyzing agents such as succinylcholine and vecuronium.** Accidental use or inadvertent use before adequate ventilation procedures were started has resulted in respiratory arrest and death.
  4. **Chemotherapy drugs.** These drugs are associated with potent adverse effects, affecting numerous body systems, such as the immune, neurologic, and clotting systems. Deaths have occurred as a result of errors with these products. For example, vincristine was accidentally given to a child instead of vinblastine, resulting in death. Confusion over the dosing of cyclophosphamide resulted in a fatal fourfold overdose.

## V. SEVERAL SAFETY TECHNIQUES OBSERVED IN COMMUNITY PHARMACIES<sup>4</sup>

- A. Keep work procedures organized and simplified.
- B. Do not work on several prescriptions at once, just one at a time.
- C. Manage interruptions, do not be pressured to rush.
- D. Smell check.
- E. Bar code check.
- F. Use a magnifying glass when needed.
- G. Enhance the design of the facility.

**VI. ROOT CAUSE ANALYSIS (RCA).** This is a structured process for identifying direct and indirect factors that contributed to a medication error. The Joint Commission presents a “Framework for Conducting an RCA and Action Plan” that can be downloaded at [http://www.jointcommission.org/Framework\\_for\\_Conducting\\_a\\_Root\\_Cause\\_Analysis\\_and\\_Action\\_Plan/](http://www.jointcommission.org/Framework_for_Conducting_a_Root_Cause_Analysis_and_Action_Plan/).

- A. Important questions to ask:
  1. What happened and why?
  2. What were the contributing factors?
    - a. Age? Hours worked? Staffing?
    - b. Workload? Stress? Confusing names? Location on shelf?
    - c. Inadequate information? Communication?
    - d. Inadequate equipment?

<sup>4</sup>Flynn EA, Barker KN, Carnahan BJ. National observational study of prescription dispensing accuracy and safety in 50 pharmacies. *J Am Pharm Assoc.* 2003;43(2):191–200.

- e. Workplace atmosphere conducive to safety?
  - f. Inadequate training of pharmacist or technician?
- B. Latent defect.** A **weakness in a system** that does not immediately result in an error but, under the right set of circumstances, can contribute to a mistake. For example:
1. **Stocking** look-alike or sound-alike drugs next to each other, contributing to a pharmacist incorrectly filling a prescription
  2. **Inadequate training** of employees, contributing to an error in which an automated dispensing machine was used improperly and a patient received the wrong medication

## VII. NATIONAL SAFETY EFFORTS

- A.** The Joint Commission's current National Patient Safety Goals for Accredited Organizations can be found at [http://www.jointcommission.org/mobile/standards\\_information/national\\_patient\\_safety\\_goals.aspx](http://www.jointcommission.org/mobile/standards_information/national_patient_safety_goals.aspx). Hospital goals include:
1. Improve the accuracy of patient identification. Have two means of identifying the patient other than room number.
  2. Improve communication among caregivers. Verify and read back telephone and oral orders.
  3. Create a list of "do not use" abbreviations. Standardize the abbreviations used, and prohibit the use of those that are prone to confusion and misinterpretation.
  4. Improve the safe use of medicines.
    - a. Limit the number of different concentrations available per drug product; standardize.
    - b. Develop methods of identifying and reviewing sound-alike and look-alike drugs, preventing errors with them.
    - c. All medications and containers should be properly labeled.
    - d. Reduce the likelihood of patient harm associated with the use of anticoagulation therapy.
  5. Reduce the risk of infections.
    - a. Comply with all Centers for Disease Control and Prevention (CDC) recommendations for hand washing and hygiene.
    - b. Thoroughly investigate all serious adverse events and deaths associated with infection acquired in a health care setting.
  6. Keep accurate patient medication records and histories throughout the continuum of care.
    - a. Ensure that a patient's medication records are complete and accurate when he or she is referred or transferred within or between organizations.
    - b. Proper communication of accurate patient medication information is critical for everyone involved in the patient's care.
- B.** The *5 Million Lives Campaign* initiated by the Institute for Healthcare Improvement can be found at <http://www.ihl.org/IHI/Programs/Campaign>.
1. Purpose: "To protect patients from **five million incidents of medical harm** over the next two years (December, 2006 to December, 2008)."
  2. Twelve interventions were identified and can be found described in more detail at the aforementioned Web site. The interventions included:
    - a. Preventing **adverse drug events** through **medication reconciliation**
    - b. Preventing **surgical site infections** by **appropriate care and antibiotic use**
    - c. Focusing on preventing harm from **high-risk medications** such as anticoagulants, sedatives, narcotics, and insulin
    - d. Reducing **methicillin-resistant *Staphylococcus aureus* (MSRA) infections** through appropriate **evidence-based practices**
- C.** The IOM in July 2006 released its report "Preventing Medication Errors." Several recommendations were made to improve patient safety including enhancing role of patient in medication management, improving patient education, and increasing the use of technology, such as e-prescribing. This report can be accessed at <http://www.iom.edu> by searching for "Preventing Medication Errors."
- D. Medication error reporting.** The reporting of medication errors provides critical safety feedback. The ISMP Medication Error Reporting Program (MERP) provides an online, confidential means of error reporting. According to the ISMP, the inclusion of the reporter's identity and location is optional. The information is shared with the FDA's MedWatch program as well as with the manufacturer/labeler. The Web site is located at <https://www.ismp.org/orderforms/reporterrortoismp.asp>.

- E. The Sorry Works Coalition (<http://www.sorryworks.net>) is an organization of various individuals (health care professionals, lawyers, insurance executives, concerned citizens, etc.) who promote the necessity of **disclosure and apology** following error. The coalition provides training and education programs.
- F. The Institute for Safe Medication Practices (<http://www.ismp.org>) focuses its efforts on **medication error prevention and patient safety**. The ISMP publishes four different safety newsletters, provides consulting services, and presents numerous educational programs, services, safety recommendations, and activities.
- G. The National Patient Safety Foundation (<http://www.npsf.org>) represents **stakeholders from a broad array of disciplines**, including patients and families. The NPSF mission is focused on **improving patient safety**. It provides numerous resources, publications, and activities directed at improving the care of patients.
- H. The Institute for Healthcare Improvement (IHI) has created the IHI “Open School” at <http://www.ihi.org/offering/IHIOpenSchool/Pages/default.aspx>. Online modules regarding patient safety and quality assurance are available. Additional resources and material are provided. Student chapters of the Open School exist and information is provided on how to initiate these chapters.

## Study Questions

**Directions:** Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. A major result in the 2000 Institute of Medicine (IOM) report is that
  - (A) pharmacists are not blamed for most medical errors.
  - (B) surgeons make more mistakes than any other health professional.
  - (C) pharmacists make more mistakes than any other health professional.
  - (D) there is now more emphasis on error prevention.
2. A pharmacist is presented a prescription for 250 mcg of levothyroxine. Which of the following dosages would be equivalent to that amount?
  - (A) 2.5 mg
  - (B) 0.25 g
  - (C) 0.25 mg
  - (D) 25 g
3. A prescription is written for warfarin 1.0 mg. The community pharmacist accidentally dispenses 10 mg. The patient develops severe bleeding within 3 days and nearly dies. Which of the following is the most accurate assessment of this prescription?
  - (A) A trailing zero is present in this prescription and could have contributed to the pharmacist's error.
  - (B) This is an example of a leading zero, which contributed to the error and the patient tragedy.
  - (C) Sound-alike medications contributed to this error.
  - (D) This does not qualify as an error based on the National Coordinating Council for Medication Error Reporting and Prevention (NCCMERP) definition.
4. A hospital pharmacy begins stocking new intravenous mini-bags of a neuromuscular-blocking agent. The packaging is similar to a commonly used intravenous antibiotic. The addition of the new mini-bags was not widely communicated to all personnel. One weekend, several doses of this new product were accidentally dispensed in place of the intended doses of antibiotic. Several patients suffered respiratory arrest and one of the patients eventually died. What would a root cause analysis of this error find?
  - (A) The only cause of this error was a pharmacist who was not paying attention. The pharmacist should be dismissed.
  - (B) Poor communication practices is a latent defect in this pharmacy system and significantly contributed to the error.
  - (C) The pharmacy technicians are to blame for this error, not the pharmacist, because the technicians obtained the mini-bags from stock and placed the labels on the bags. The pharmacist checked only the technician's work. The technician should be dismissed.
  - (D) This is an example of an extra dose error.

5. What do the following abbreviations MS, MSO<sub>4</sub>, and MgSO<sub>4</sub> have in common?
- (A) Common abbreviations for morphine sulfate
  - (B) Common abbreviations for magnesium sulfate
  - (C) Should not be used in the Joint Commission–accredited institutions
  - (D) Approved abbreviations in most hospitals
6. A major error in a hospital pharmacy resulted in a total parenteral nutrition solution being mistaken for a cardioplegic solution for coronary bypass surgery. Which of the following is true regarding the root cause analysis that was done at the hospital after the error?
- (A) The primary objective is to find out which pharmacist made the mistake that allowed this to take place.
  - (B) The result of the analysis would be the admission that an error had taken place.
  - (C) All factors that could have contributed to this error would be identified and analyzed.
  - (D) A root cause analysis would be inappropriate in this case.

## Answers and Explanations

---

**1. The correct answer is D [see I.A.2].**

The IOM report revealed alarming data on deaths related to medical errors. The report contributed to increased efforts to improve patient safety.

**2. The correct answer is C [see III.D].**

Although this may seem to be an elementary question and answer, a wrong dose error such as this could easily lead to a serious injury or death to a patient.

**3. The correct answer is A [see IV.A.4].**

Warfarin 1.0 mg is an example of a trailing zero. The Joint Commission has included this in its “do not use” list of abbreviations. However, in the community setting, it is a practice that can still be frequently seen on prescriptions. When a trailing zero is observed, much caution should be exercised in interpreting the prescription.

**4. The correct answer is B [see VI.A.2].**

Poor communication was a major contributing factor to this tragic series of errors. The drug was a high-risk drug and had similar packaging as another commonly used drug. These are two major ingredients for the serious error that took place. This does not absolve

the technician and pharmacist totally from any blame but emphasizes the significant role that failure of communication played within this pharmacy system. The system was as much or more to blame than any individuals. Firing the individuals does not repair the problem of poor communication in the system but only sets the stage for a similar mistake to occur again.

**5. The correct answer is C [see IV.A.6].**

These abbreviations are included in the Joint Commission’s “do not use” list. Errors resulting in serious harm have occurred after mix-ups with morphine and magnesium.

**6. The correct answer is C [see VI.A.2].**

A root cause analysis is not intended to focus on blame but on all factors that could have been related to this error. Factors might have included training of pharmacist and technicians, the actual drug order, and the label. The contribution of such factors might not be discovered if the focus is on only identifying which pharmacist, technician, or other professional is to blame.

JAMES A. BOYD

## I. FEDERAL CONTROLLED SUBSTANCES ACT

**A. Schedules of controlled substances.** Certain drugs have a potential for abuse that leads to physical or psychological dependence. As a result, the U.S. federal government has placed these drugs into Schedules (I, II, III, IV, and V) and refers to them as controlled substances. The Attorney General of the United States has the authority to add or remove a drug or substance from one of the federal Schedules, or to transfer a drug from one federal Schedule to another. The federal Schedules are updated and published annually by the federal government.

1. **Schedule I (CI; C-I).** Schedule I drugs may not be kept in a pharmacy nor dispensed pursuant to a prescription (except for properly registered facilities for investigative or research purposes). A controlled substance analogue of a drug in any Federal Schedule, commonly referred to as a “designer drug,” is considered a Schedule I substance to the extent intended for human consumption. Required findings by the government for placement of a drug into Schedule I include:
  - a. The drug or other substance has a high potential for abuse.
  - b. The drug or other substance has no currently accepted medical use in treatment in the United States.
  - c. There is a lack of accepted safety for use of the drug or other substance under medical supervision.
2. **Schedule II (CII; C-II).** Required findings for placement of a drug into Schedule II include:
  - a. The drug or other substance has a high potential for abuse.
  - b. The drug or other substance has a currently accepted medical use in treatment in the United States or a currently accepted medical use with severe restrictions.
  - c. Abuse of the drug or other substance may lead to severe psychological or physical dependence.
3. **Schedule III (CIII; C-III).** Required findings for placement of a drug into Schedule III include:
  - a. The drug or other substance has a potential for abuse less than the drugs or other substances in Schedules I and II.
  - b. The drug or other substance has a currently accepted medical use in treatment in the United States.
  - c. Abuse of the drug or other substance may lead to moderate or low physical dependence or high psychological dependence.
4. **Schedule IV (CIV; C-IV).** Required findings for placement of a drug into Schedule IV include:
  - a. The drug or other substance has a low potential for abuse relative to the drugs or other substances in Schedule III.
  - b. The drug or other substance has a currently accepted medical use in treatment in the United States.
  - c. Abuse of the drug or other substance may lead to limited physical dependence or psychological dependence relative to the drugs or other substances in Schedule III.
5. **Schedule V (CV; C-V).** Required findings for placement of a drug into Schedule V include:
  - a. The drug or other substance has a low potential for abuse relative to the drugs or other substances in Schedule IV.
  - b. The drug or other substance has a currently accepted medical use in treatment in the United States.

- c. Abuse of the drug or other substance may lead to limited physical dependence or psychological dependence relative to the drugs or other substances in Schedule IV.
- B. Registration requirements.** The Federal Controlled Substances Act regulates the use of controlled substances by requiring all entities that lawfully handle them to register with the federal government, specifically, the Drug Enforcement Administration (DEA).
1. **Entities that must register**
    - a. **Manufacturers and wholesalers** of controlled substances must register with the DEA initially and reregister every year thereafter.
    - b. **Dispensers** (practitioners and pharmacies) of controlled substances must register with the DEA initially and reregister every 3 years thereafter. Pharmacists, pharmacy interns, pharmacy technicians, and all other employees or agents of a pharmacy do not have to register, providing the pharmacy is properly registered and the employee or agent is acting in the usual course of employment or business.
    - c. All other entities that lawfully handle any controlled substance must register with the DEA, including researchers, clinics and laboratories, and teaching institutions.
  2. **Separate registration for separate activities.** Every entity that engages in one of the following activities must register with the DEA. A separate registration is required for each activity, with certain exceptions (e.g., a manufacturer of a Schedule of a controlled substance is allowed to distribute that Schedule without being registered as a distributor).
    - a. Manufacturing controlled substances
    - b. Distributing controlled substances
    - c. Dispensing controlled substances listed in Schedules II to V (e.g., practitioners, pharmacies)
    - d. Conducting research with controlled substances listed in Schedules II to V
    - e. Conducting instructional activities with controlled substances listed in Schedules II to V
    - f. Conducting a narcotic treatment program using any narcotic drug listed in Schedules II, III, IV, or V
    - g. Conducting research and instructional activities with controlled substances listed in Schedule I
    - h. Conducting chemical analysis with controlled substances listed in any Schedule
    - i. Importing controlled substances
    - j. Exporting controlled substances
    - k. Participating in maintenance or detoxification treatment and mixing, preparing, packaging, or changing the dosage form of a narcotic drug listed in Schedules II, III, IV, or V for use in maintenance or detoxification treatment by another narcotic treatment program.
  3. **Separate registrations for separate locations.** Each principal place of business of a registrant having more than one location must have its own registration certificate. Each pharmacy, chain pharmacy, and hospital that dispenses controlled substances must have its own registration certificate. Registration is not required for an office that is used by a registrant where controlled substances are neither stored nor dispensed.
    - a. **Warehouses.** A warehouse where controlled substances are stored by or on behalf of a registrant is not required to register unless one of the following occurs:
      - (1) Controlled substances are directly distributed from the warehouse to a registered location different from the location from which the substances were shipped.
      - (2) Controlled substances are directly distributed from the warehouse to a person or entity not required to register under the Act.
  4. **Registration procedure.** Applications to become registered must be submitted to the DEA on the appropriate form with the required fee, information, and signature of one of the following:
    - a. The individual who owns and operates the entity, if doing business as an individual.
    - b. A partner of the applicant, if a partnership.
    - c. An officer of the applicant, if a corporation, corporate division, association, trust, or other entity.
    - d. One or more individuals who have been granted a power of attorney by an applicant. A **power of attorney** allows one to lawfully act in place of another. The power of attorney must be signed by one of the individuals listed previously in a to c and by the individual receiving the power of attorney. The power of attorney remains valid until revoked by the applicant.

5. **Registration action by the DEA.** If an application is complete, it will be accepted for filing. If it is defective, the DEA will return the application with a statement indicating the reason for its nonacceptance. The application may be corrected and resubmitted at any time.
  - a. **Issuance of certificate of registration.** A certificate of registration will be issued by the DEA when it determines that the registration is required by law in order to conduct such activity (e.g., manufacturing, distributing, or dispensing a controlled substance). The certificate must be conspicuously maintained and readily retrievable at the registered location.
  - b. **Denial of registration.** If the DEA determines that a registration is not required by law, it will issue an Order To Show Cause why the registration should not be denied. The applicant may request a hearing and explain why the certificate of registration should be issued. After the hearing, the DEA may deny the application or issue the certificate.
6. **Modification of registration.** A registrant may submit a letter of request to the DEA seeking to modify its registration. A modification may be sought when there is a change in the name or address that appears on the certificate, or when the pharmacy seeks DEA approval to dispense additional controlled substances (if initially authorized to only dispense a particular Schedule[s] of controlled substances).
7. **Transfer of registration.** A registration to dispense controlled substances may not be transferred to any other person or entity except when the ownership of a pharmacy is being transferred from one entity to another. In such a case, controlled substances in Schedules II to V must be properly disposed of or transferred to the new entity.
8. **Suspension or revocation of registration.** The DEA may suspend or revoke any registration. The DEA must first issue an Order To Show Cause (upon the registrant) why the registration should not be revoked or suspended. The registrant may request a hearing to explain why the registration should not be suspended or revoked. After a hearing, the DEA may suspend, revoke, or take no action on the registration.
  - a. **Order of suspension or revocation.** After a registrant has received an order suspending or revoking its registration, it must take the following action:
    - (1) Immediately deliver its certificate of registration and any DEA 222 order forms in its possession to the nearest office of the DEA.
    - (2) As instructed by the DEA, either:
      - (a) deliver all controlled substances in its possession to the nearest office of the DEA or to authorized agents of the DEA, or
      - (b) place all controlled substances in its possession under seal.
  - b. **Imminent danger to public health or safety.** The DEA may serve on a registrant an order of immediate suspension when it finds that there is an **imminent danger** to the **public health or safety**. The immediate suspension remains in effect until the conclusion of all proceedings, either administrative proceedings by the DEA or judicial proceedings. After receiving an order of immediate suspension, the registrant must take the same action as outlined previously under I.B.8.a.
9. **Exemptions from registration.** Certain individuals are exempt from registration under the Act. The following are exempt:
  - a. **Military officials.** Military officials, including Public Health Service and Bureau of Prisons officials, who are authorized to prescribe, dispense, or administer, but not to procure or purchase, controlled substances in the course of their official duties, are exempt from registering with the DEA. The individual must, however, obtain a registration for such activities conducted during any separate private practice.
  - b. **Law enforcement officials.** Federal and state law enforcement personnel acting in the course of enforcing any law relating to controlled substances are exempt from registration.
  - c. **Civil defense officials.** Civil defense and disaster relief organization officials are exempt from registration in order to maintain and dispense controlled substances during times of proclaimed emergencies or disasters.
  - d. **Agents and employees of registrants.** Agents and employees, while acting lawfully in the usual course of their business or employment, are exempt from registration when the business or employment is conducted on behalf of a person (or business) who is registered under the Act. Delivery personnel (e.g., United Parcel Service, Federal Express) are therefore not required to register. Likewise, pharmacists working for a registered pharmacy are not required to register.

10. **Termination of registration.** The registration of any person or entity will terminate when the person dies, ceases legal existence (e.g., corporate dissolution, partnership dissolution), or discontinues business or professional practice. The DEA must be notified promptly when any of these occurs. In such a case, all controlled substances in Schedules II to V must be properly disposed of.
- C. **Required inventories.** The Act requires all pharmacies and hospitals (every separately registered location) to conduct an initial inventory and biennial inventory of all controlled substances in Schedules II, III, IV, and V.
1. **Initial inventory.** The initial inventory must be taken on the date the entity commences business and begins dispensing controlled substances. If the entity has no controlled substances on hand, a record of this fact must be maintained as its initial inventory.
  2. **Biennial inventory.** The biennial inventory must be taken at least every 2 years from the date of the initial inventory.
    - a. **Biennial date.** The biennial date may be **any** date that is within 2 years of the previous biennial (or initial) date. This date does **not** have to be reported to the DEA if it is different from the biennial date that would otherwise apply (i.e., on the exact day 2 years after the previous inventory).
  3. **Inventory procedures**
    - a. All inventories must be maintained in a **written, typewritten, or printed form** and be conducted at either the opening of business or the close of business on the inventory date (which must be noted on the inventory).
    - b. **Separate inventory record for Schedule II controlled substances.** Because all records for Schedule II controlled substances must be maintained separately from other records, Schedule II inventories must be maintained separately from other controlled substance inventories.
  4. **Inventory content.** All inventory records must contain the following:
    - a. Date the inventory is taken.
    - b. Each finished form of the substance (dosage form and strength).
    - c. Number of units or volume of each finished form in each commercial container (e.g., 100-tablet bottle). For opened commercial containers, inventory must be taken as follows:
      - (1) For Schedule II controlled substances, an exact count or measure must be taken.
      - (2) For Schedule III, IV, and V controlled substances, an estimated count or measure may be taken, except that an exact count must be taken if the container holds more than 1000 tablets or capsules.
    - d. For each controlled substance maintained for extemporaneous compounding, or for substances that are damaged, defective, or impure and awaiting disposal:
      - (1) Name of the substance
      - (2) Total quantity to the nearest metric unit weight or the total number of units of finished form
      - (3) Reason the substance is being maintained and whether it is capable of use in the manufacture of any controlled substance in finished form
  5. **Inventory record maintenance.** Every inventory record must be maintained at the registered location (e.g., pharmacy, hospital) for at least 2 years from the date of the inventory.
    - a. Schedule II inventories must be maintained separately from all other records of the pharmacy.
    - b. Schedule III to V inventory records must be maintained either separately from all other records of the pharmacy or in such a manner that the required information is readily retrievable from ordinary business records of the pharmacy. "Readily retrievable" means that the inventory records can be separated out from all other records in a reasonable time.
  6. **Perpetual inventories.** The Act does not require a dispenser registrant (e.g., pharmacy, hospital) to maintain a perpetual inventory of any controlled substance.
  7. **Newly controlled substances or changes in scheduling of a substance.** An inventory of a substance must be taken when, by order of the DEA, it becomes a newly controlled substance or it shifts into another Schedule. The inventory of that particular controlled substance must be taken on the effective date of the change. A complete inventory of all controlled substances is not required, nor is an inventory required when a substance moves from a controlled substance Schedule to a nonfederal Schedule.

8. **Transfer of business activity.** An inventory of controlled substances II to V must be taken at the time a pharmacy or hospital undergoes a change in ownership. The inventory must be taken on the date of transfer and serves as the final inventory of the transferor and the initial inventory of the transferee.
  9. **Inventory record submission.** The Act does not require the submission of inventory records to anyone, including the DEA. The records must be maintained at the registered location for inspection and copying by authorized agents of the DEA.
- D. Obtaining controlled substances.** Schedule II controlled substances must be obtained from a supplier (wholesaler, manufacturer) by using DEA Form 222. The Act does not require the use of any special form to obtain controlled substances in Schedules III to V.
1. **DEA Form 222.** Only entities that are registered to dispense or handle Schedule II controlled substances may obtain Form 222. The forms are serially numbered and issued by the DEA with the name, address, registration number, authorized activity, and Schedules of the registrant. Each form contains an original, duplicate, and triplicate copy (Copy 1, Copy 2, and Copy 3, respectively).
  - a. **Execution of Form 222.** Form 222 may be executed only on behalf of the registrant named on the form and only if the registration has not expired nor been revoked or suspended. The form must be prepared in triplicate as provided by the DEA by use of a typewriter, pen, or indelible pencil in the following manner:
    - (1) Only one item may be ordered on each of the 10 numbered lines on the form. The total number of items ordered must be noted on the form in the space provided.
    - (2) One item may consist of one or more commercial or bulk containers of a product. A separate item must be made for different commercial or bulk containers of a product. For each item, the form must contain the following information:
      - (a) Name of the article ordered
      - (b) Finished or bulk form of the product (dosage form and strength)
      - (c) Number of units or volume in each commercial or bulk container (e.g., 100-tablet bottle)
      - (d) Number of commercial or bulk containers ordered
      - (e) If the article is not in pure form, the name and quantity per unit of the controlled substances contained in the article.
    - (3) The supplier's name and address must be included on the form. Only one supplier may be listed on any one form.
    - (4) Each form must include the date of the order, and no form is valid more than 60 days after its execution by the purchaser.
    - (5) The form must be signed either by the person who signed the most recent application for registration or reregistration, or by a person authorized to obtain and execute order forms by a **power of attorney**.
      - (a) Any purchaser may authorize one or more individuals (does not have to be an attorney-at-law), whether or not located at the registered location, to obtain and execute 222 Forms by executing a power of attorney for the individual(s).
      - (b) The power of attorney must be signed by the person who signed the most recent application for registration or reregistration and by the individual(s) receiving the power of attorney. This form must be similar or identical to the DEA's "Power of Attorney for DEA Order Forms."
      - (c) Once properly executed, the individual receiving the power of attorney may obtain and sign DEA Form 222 to the same extent as the individual who signed the most recent application for registration or reregistration.
      - (d) The power of attorney must be filed with the executed 222 Forms of the purchaser and be retained for the same period as any order form bearing the signature of the attorney (see I.D.1.a.[8]). The power of attorney does not have to be submitted to the DEA.
    - (6) Copies 1 and 2 must be submitted to the supplier. Copy 3 must be retained by the purchaser.
    - (7) When the ordered Schedule II controlled substances are received by the pharmacy, the following information must be recorded on the retained Copy 3:
      - (a) Number of commercial or bulk containers furnished on each item (or line)
      - (b) Date on which the containers are received by the pharmacy

- (8) DEA 222 Forms must be maintained at the registered location (pharmacy or hospital) for at least 2 years from their execution. The time of execution would be the date the last entry was made on Copy 3.
- b. Cancellation by purchaser.** A purchaser may cancel all or part of an order by notifying the supplier in writing. The supplier must indicate the cancellation on Copies 1 and 2 by drawing a line through the canceled items and printing the word “canceled” in the space provided for number of items shipped. Likewise, a supplier may void all or part of an order by notifying the purchaser in writing and printing the word “canceled” in the space provided for number of items shipped.
  - c. Maintenance of DEA Form 222.** Executed Copy 3 forms and Copies 1 and 2 of each unaccepted or defective form and the statement of refusal from the supplier must be maintained by the purchaser. They must be kept separate from all other records and be available for inspection for at least 2 years. All forms must be maintained at the registered location preprinted on the form, and not at a central location.
  - d. Loss or theft of DEA Form 222.** Any used or unused form stolen from or lost by a purchaser or supplier must be reported immediately to the DEA. Such notification must include the serial number of each form lost or stolen.
- 2. Electronic DEA Order System (CSOS).** The DEA provides an electronic ordering system in addition to the DEA Form 222. Pharmacies wishing to order Schedule I and II drugs online must apply for a digital certificate for signing the order, and a digital certificate is issued for each location with a DEA registration. This requirement ensures each pharmacy location has an individual identification. The agency does not give a central registration for multiple locations (i.e., one registration serving multiple pharmacies [chains]). One registration can have more than one certificate if multiple people have power of attorney. One distinct difference with the CSOS compared to the DEA Form 222 is that the CSOS is not limited to Schedule I and Schedule II drugs. The electronic system allows registrants to orders Schedules III, IV, and V drugs and noncontrolled substances.
- 3. Obtaining Schedule III to V controlled substances.** There is no special form for obtaining Schedule III to V controlled substances. Each registrant must, however, maintain a complete and accurate record of receipt for each such substance. The record must be maintained at either the registered location of the pharmacy or hospital, or at a central location, for 2 years. If a central location is used, the pharmacy must first notify the DEA, indicating its intention to keep central records. Central records may then be maintained unless the DEA denies the request to keep such records. An invoice or packing slip will suffice as a record of receipt, providing the following information is included:
- a.** Name of the controlled substance
  - b.** Finished form of the substance (dosage form and strength)
  - c.** Number of units or volume of the finished form in each commercial container (e.g., 100-tablet bottle)
  - d.** Number of commercial containers of each such finished form received from other persons
  - e.** Date of actual receipt of each commercial container
  - f.** Name, address, and registration number of the person from whom the containers were received
- E. Storage of controlled substances.** All controlled substances in Schedules II to V must be stored in one of the following ways:
- 1.** In a securely locked, substantially constructed cabinet
  - 2.** Dispersed throughout the stock of un-Scheduled prescription medication to prevent any theft or diversion
- F. Theft or significant loss of Schedule II to V controlled substances.** Every registrant must promptly notify the regional office of the DEA of the theft or significant loss of any controlled substance in Schedules II to V. This report must be done using DEA **Form 106**.
- G. Disposal of controlled substances.** Every disposal of a controlled substance must be accomplished by submitting DEA **Form 41** to the DEA (except for disposals pursuant to a valid prescription, discussed in the succeeding text). The form must list the controlled substances earmarked for disposal. The DEA will authorize the disposal and instruct the registrant to dispose of the controlled substances in one of the following ways:
- 1.** By the transfer to a person or entity registered with the DEA and authorized to possess the substance. Schedule II controlled substances must be transferred by the use of the transferee’s

(another pharmacy or hospital, or the wholesaler or manufacturer) DEA Form 222. A written record of the transfer of Schedule III to V controlled substances must be kept for at least 2 years and include the following information:

- a. Name of the controlled substance
  - b. Finished form of the substance (dosage form and strength)
  - c. Number of units or volume of the finished form in each commercial container (e.g., 100-tablet bottle)
  - d. Number of commercial containers of each finished form transferred
  - e. Date of the transfer
  - f. Name, address, and registration number of the transferee
2. By the delivery to an agent of the DEA or to the nearest office of the DEA
  3. By the destruction in the presence of an agent of the DEA or other authorized person
  4. By any other means that the DEA determines to ensure that the substance does not become available to unauthorized persons or entities

**H. Regular disposals of controlled substances.** If a registrant (usually a hospital) regularly disposes of controlled substances in Schedules II to V, the DEA may authorize disposals without prior approval in each instance. If the DEA grants this authority, the registrant must keep records of each disposal and file periodic reports to the regional office of the DEA summarizing the disposals. The DEA may place additional conditions on such disposal, including the method of disposal and the frequency and detail of reports.

**I. Dispensing of controlled substances pursuant to a valid prescription**

**1. Persons who may issue prescriptions for controlled substances.** A controlled substance prescription may be issued only by a practitioner who is granted such authority by the state in which that practitioner is licensed. Although the Act is federal legislation, each state determines who will be authorized to dispense controlled substances. Most states allow the following individuals to prescribe: physicians, dentists, podiatrists, and veterinarians. Some states allow the following individuals, referred to as midlevel practitioners, to prescribe (usually with certain restrictions): physician's assistants, nurse practitioners, certified nurse midwives, psychiatric nurses, and mental health clinical specialists. All prescribers must be registered with the DEA or exempted from registration (see I.B.9). **Practitioner** means a physician, dentist, veterinarian, or other person licensed (midlevel practitioners) by the state to prescribe controlled substances, **and** pharmacy, hospital, or other institution licensed to distribute controlled substances. **Individual practitioner** means a physician, dentist, veterinarian, or other person licensed (midlevel practitioners) by the state to prescribe controlled substances. It is worth noting that the term "individual practitioner" is included in the definition of "practitioner." Prescribing authority granted by states is limited to professionals within the "individual practitioner" category. The statement such as "practitioner who is granted prescribing authority" means the "individual practitioner" who has been granted prescribing authority by the state because the individual practitioner is included in the definition of practitioner. "Pharmacy" is defined as a "practitioner" but, of course, does not have prescribing authority.

**a. DEA numbers and authenticity.** After registering with the DEA, all registrants are assigned a DEA number by the DEA. A practitioner's DEA number consists of nine characters. The first two characters are letters. The first letter will be either A or B. The second letter will be the first letter of the practitioner's last name. The next six characters are randomly chosen numbers. The last character is a number often referred to as the "check digit." For example, Dr. Henry Jones may have a DEA number of AJ 4357782.

**(1) Authentication of DEA number.** The DEA assigns DEA numbers with a quick method of verification built into the number. This allows a dispensing pharmacist to make a cursory review of the number for authenticity. For example, using the aforementioned DEA number, the practitioner's last name must start with a "J." Also, the following quick calculation can be made to verify that the "check digit" is correct:

- (a) The digits in positions 1, 3, and 5 are added together to reach a number. In the previous example, that would be  $4 + 5 + 7 = 16$ .
- (b) The digits in positions 2, 4, and 6 are added together, then multiplied by 2. In the previous example, that would be  $(3 + 7 + 8) \times 2 = 36$ .

- (c) These aforementioned numbers are added together:  $16 + 36 = 52$ . The far-right digit becomes the check digit. The check digit must therefore be a 2. If the check digit is anything other than a 2, the number may not be a valid DEA number. In such a case, the DEA should be notified in order to verify the number.
- (2) **Midlevel practitioner DEA numbers.** Midlevel practitioner DEA numbers are similar to practitioner DEA numbers except for the first character. Instead of the letter A or B, midlevel practitioners have the letter M as the first character in their DEA number. The mathematical method for verifying the authenticity of the number is the same.
- (3) **DEA numbers for practitioners and midlevel practitioners who are employees of institutions.** Practitioners and midlevel practitioners who issue prescriptions in the course of their employment with an institution may issue prescriptions for all controlled substances under the institution's DEA registration. The practitioner's or midlevel practitioner's "DEA number" will be a specific internal code number issued by the institution. The code number must consist of numbers, letters, or a combination of numbers and letters and must be a suffix to the institution's DEA number, preceded by a hyphen (e.g., AP0123456-10 or AP0123456-A12).
2. **Purpose of issuance of controlled substance prescriptions.** A controlled substance prescription may be issued only in good faith for a legitimate medical purpose by a practitioner acting in the usual course of his or her professional practice. The practitioner and the dispensing pharmacist have the responsibility to ensure that a prescription is properly issued and dispensed (referred to as corresponding responsibility of the pharmacist).
- a. **Legitimate medical purpose.** Legitimate medical purpose and good faith are prerequisites for all controlled substance prescriptions. With respect to a pharmacist, these requirements will be apparent from an objective point of view. As a general rule, if, from all the surrounding facts and circumstances, a reasonably prudent pharmacist would form the opinion that a prescription was issued for a legitimate medical purpose, then the pharmacist has fulfilled his or her responsibility under the Act, and the prescription may be legally dispensed.
- b. **Usual course of professional practice.** A **practitioner-patient relationship** for the purpose of treating and caring for the patient must be present. Usually, such a relationship includes the taking and recording of an appropriate medical history, and an appropriate physical exam. This limits a practitioner's ability to prescribe outside his or her course of professional practice (e.g., a veterinarian may not prescribe a controlled substance for a human). The notion of "usual course of practice" becomes more unclear with respect to medical doctors who specialize. Such specialists often issue prescriptions "outside" their specialty. Generally, all controlled substance prescriptions from medical doctors are deemed to be "in the usual course of professional practice" as long as it is issued for a human, regardless of whether the problem being treated is within the doctor's specialty.
- c. **Restrictions on issuance of a controlled substance prescription**
- (1) A prescription may not be issued by a practitioner in order for that practitioner to obtain controlled substances for the purpose of **general dispensing** to his or her patients.
- (2) A prescription may not be issued for the dispensing of controlled substances for **detoxification** or maintenance treatment. Administration and direct dispensing of controlled substances are allowed only when conducted in properly registered treatment programs. A prescription for **methadone** is valid only when issued as an analgesic in cases of severe pain. Methadone may be dispensed in a hospital to maintain a patient's addiction as long as the patient is admitted and being treated for some other medical condition and is not administered methadone solely for detoxification purposes. The 40 mg tablets of methadone are only available to hospitals and facilities authorized for detoxification and maintenance treatment of opioid addiction. The other strengths (5 mg and 10 mg formulations) indicated for the treatment of pain are available to all authorized registrants, including retail pharmacies.
3. **Manner of issuance of a controlled substance prescription.** Schedule II controlled substance prescriptions must be written with ink or indelible pencil or typewritten (except in cases of oral emergency Schedule II prescriptions). Schedule III to V controlled substance prescriptions may be orally ordered by the practitioner. Prescriptions may be prepared by either the practitioner or

an agent of the practitioner, and communicated to the pharmacy by the practitioner or the agent. Authorization for the prescription (or refill) must, however, originate with the practitioner. Both the practitioner and dispensing pharmacist are responsible for the completeness of the prescription. All prescriptions for controlled substances must include the following information:

- a. Full name and address of the patient
  - b. Date the prescription is issued and signed (one and the same)
  - c. Drug name, dosage form, and strength
  - d. Quantity of drug prescribed
  - e. Directions for use
  - f. Name, address, and DEA registration number of the practitioner
  - g. The signature of the practitioner (no preprinted or stamped signatures) as he or she would sign any legal document (all Schedule II controlled substance prescriptions must be manually signed by the practitioner)
4. **Emergency dispensing of Schedule II controlled substances**
- a. An oral Schedule II controlled substance prescription may be received from a practitioner in an emergency situation. An emergency prescription must include all of the information required for any controlled substance prescription. An emergency situation exists when **all three** of the following factors are present:
    - (1) The immediate administration of the controlled substance is necessary for proper treatment of the patient.
    - (2) No appropriate alternative treatment is available, including administration of a controlled substance that is not in Schedule II.
    - (3) It is not reasonably possible for the practitioner to provide a written prescription to be presented to the person dispensing the controlled substance before the dispensing.
  - b. **Proper dispensing.** The quantity prescribed and dispensed must be limited to the amount necessary to adequately treat the patient during the emergency period. If the practitioner is not known to the pharmacist, the pharmacist must make a reasonable good-faith effort to determine that the oral authorization came from a registered practitioner.
    - (1) **Delivery of written prescription.** The practitioner who authorizes the emergency prescription must, within 7 days of the oral authorization, deliver a written prescription to the dispensing pharmacist. The prescription must contain the information required of all controlled substance prescriptions, have written on its face the words “Authorization for Emergency Dispensing,” and the date of the oral authorization. The prescription may be delivered in person or by mail; if delivered by mail, it must be postmarked within the 7-day period. Upon receipt, the dispensing pharmacist must attach it to the oral emergency prescription, which was previously reduced to writing.
    - (2) **Failure to deliver a written prescription.** If a practitioner fails to deliver the written prescription as required, the dispensing pharmacist must notify the regional office of the DEA. Failure by the pharmacist to notify the DEA serves to void the pharmacist’s authority to dispense an oral emergency Schedule II prescription. The pharmacist will be deemed to have unlawfully dispensed a Schedule II controlled substance.
5. **Facsimile prescriptions.** Prescriptions for controlled substances III, IV, and V (and nonfederal controlled substances such as penicillin and furosemide) may be delivered to the dispensing pharmacy via facsimile machine. A facsimile prescription is deemed to be the written, signed prescription from the prescriber so long as it contains the information required of all prescriptions under federal law. The prescription must be sent directly from the prescriber or his or her authorized agent to the pharmacy.
- a. **Schedule II controlled substances.** Prescriptions for Schedule II controlled substances may be sent via facsimile to a dispensing pharmacy to facilitate dispensing of the prescription. **No drug may be released** to the patient until the original, signed prescription is presented to the dispensing pharmacist. A Schedule II controlled substance facsimile prescription **will serve** as the original, signed prescription in the following situations:
    - (1) **Injectable home health prescriptions.** A facsimile Schedule II narcotic prescription calling for the compounding of a solution for direct administration to a patient in a private residence, long-term care facility, or hospice setting may serve as the original prescription.

The exception applies so long as the solution will be administered by means of parenteral, intravenous, intramuscular, subcutaneous, or intraspinal infusion.

- (2) **Long-term care facility prescriptions.** Any facsimile Schedule II prescription issued for a resident of a long-term care facility may serve as the original, signed prescription.
  - (3) **Hospice patient prescriptions.** Any facsimile Schedule II narcotic prescription issued for a patient enrolled in a hospice care program certified and/or paid for by Medicare under Title XVIII or licensed by state law may serve as the original prescription. The prescriber, or his or her agent, **must** note on the prescription that the patient is a hospice patient.
6. **Electronic data transmission prescriptions for noncontrolled substances.** Prescription information that is transmitted directly from a practitioner to a pharmacy by electronic means such as via the Internet is referred to as **electronic data transmission prescription**. Electronic signatures are recognized as legally acceptable signatures of practitioners. Legend drugs, except for controlled substances, may be transmitted to pharmacies via the Internet if allowed by state law. A state may allow a practitioner and pharmacy to maintain the prescription information in electronic form without reducing it to writing, so long as they comply with state-mandated safeguards.
- a. **Electronic data transmission prescriptions for controlled substances.** The DEA does not yet recognize electronic data transmission prescriptions as a means of communicating prescription information for any controlled substance. Therefore, prescription information for controlled substances may not be communicated from a practitioner to a pharmacy by electronic means.
7. **Persons who may dispense controlled substance prescriptions.** A **pharmacist** acting in the usual course of his or her professional practice in a DEA-registered pharmacy (or hospital or other registered facility) may dispense a controlled substance pursuant to a prescription. A **pharmacy intern** acting under the direct supervision of his or her preceptor in a DEA-registered facility may also dispense a controlled substance pursuant to a prescription.
8. **Dispensing procedures of controlled substances pursuant to a prescription.** Once a controlled substance prescription has been lawfully issued by a practitioner and presented to a pharmacist, it may be dispensed in accordance with the following:
- a. **Presentation to the pharmacist.** Schedules III and IV controlled substance prescriptions are valid for 6 months from the date of issuance by the practitioner. Schedule II controlled substance prescriptions have no time limit for presentation under the Act, although they are often recognized to be valid for up to 6 months. Schedule V controlled substance prescriptions also have no set time limit for presentation under the Act. Regardless of which Schedule of controlled substance is involved, the good-faith and “legitimate medical purpose” limitation will always apply and may serve to otherwise limit the validity of a prescription.
  - b. **Information that must be recorded on the prescription by the dispensing pharmacist.** Under the Act, a filled prescription is considered to be a lawful record of disposition for a controlled substance. As a result, every prescription for a controlled substance must contain certain information. Some of the information will already be contained in the prescription, although the dispensing pharmacist is responsible for ensuring that all of the following information is recorded (usually on the face of the prescription):
    - (1) Name of the controlled substance
    - (2) Finished form of the controlled substance (dosage form and strength)
    - (3) Name and address of the person to whom it was dispensed
    - (4) Date of dispensing
    - (5) Number of units or volume dispensed (quantity)
    - (6) Written or typewritten name or initials of the individual who dispensed the controlled substance
    - (7) Serial number of the prescription
  - c. **Required information on prescription labels.** Every prescription label for a controlled substance must include the following information:
    - (1) Name and address of the pharmacy
    - (2) Serial number assigned to the prescription
    - (3) Date of the initial filling of the prescription (for refills, the date originally filled)

- (4) Name of the patient
  - (5) Name of the prescribing practitioner
  - (6) Directions for use, and cautionary statements, if any
  - (7) For Schedule II, III, and IV controlled substances, the federal crime transfer warning must appear on the container: "Caution: Federal law prohibits the transfer of this drug to any person other than the patient for whom it was prescribed."
- d. **Allowable quantities that may be dispensed.** The Act contains no limitation concerning the quantity of a controlled substance that may be dispensed pursuant to a prescription. All quantities are, of course, limited to the good-faith and "legitimate medical purpose" standards.
- e. **Filing controlled substance prescriptions.** Written controlled substance prescriptions must be maintained at the pharmacy for a period of 2 years from the date of the original dispensing or last refill, whichever is later. They must be available for inspection and copying by employees and agents of the DEA and be filed **segregated** from all other records in one of the following ways (state law usually dictates the method to be used):
- (1) Using **three separate files** as follows:
    - (a) One file for Schedule II controlled substance prescriptions
    - (b) One file for Schedule III, IV, and V controlled substance prescriptions
    - (c) One file for un-Scheduled prescription drugs
  - (2) Using **two separate files** as follows:
    - (a) One file for all controlled substance prescriptions (II to V), as long as Schedule III, IV, and V prescriptions have the letter "C" stamped in red ink in the lower right corner no less than 1 inch high
    - (b) One file for un-Scheduled prescription drugs
  - (3) Using **two separate files** as follows:
    - (a) One file for Schedule II controlled substance prescriptions
    - (b) One file for all other controlled substances (III to V) and un-Scheduled prescription drugs, as long as Schedule III, IV, and V prescriptions have the letter "C" stamped in red ink in the lower right corner no less than 1 inch high
  - (4) In either (2) or (3) earlier, if a pharmacy uses an electronic record-keeping system for prescriptions (i.e., computerized records) that permits identification by prescription number and retrieval of original documents by prescriber's name, patient's name, drug dispensed, and date filled, then the requirement to mark the hard copy prescription with a red "C" is waived.
- f. **Refill dispensing of controlled substances.** Prescriptions for Schedule II controlled substances may not be refilled. Prescriptions for Schedules III and IV controlled substances may be refilled up to five times within 6 months from the date of issue of the prescription. Schedule V controlled substance prescriptions have no limitations for refilling under the Act; however, once again, the good-faith and "legitimate medical purpose" limitations apply here, as well as to all controlled substance refills.
- (1) Refill information may be maintained either manually or by the use of a computer. The Act requires that the information be maintained one way or the other, but not both ways. If **computerized refill records** are maintained, the system must have certain capabilities and the dispensing pharmacist must follow certain procedures.
    - (a) The computer must be able to provide online retrieval of the original prescription information, online retrieval of the refill history, a refill-by-refill audit trail, and an auxiliary procedure in those cases where the system experiences downtime.
    - (b) The system must also allow the pharmacist who refills a prescription to document that the information he or she entered into the computer is correct.
  - (2) When dispensing a refill, the pharmacist must record, on the back of the original prescription or by computer, the following information:
    - (a) Date of the refill
    - (b) Name or initials of the refilling pharmacist
    - (c) Amount of the medication dispensed (if the amount is omitted, the refill will be deemed to have been for the full face amount prescribed by the practitioner)

- g. Multiple Schedule II prescriptions prescribed on the same day to be filled sequentially.** The refill of a prescription for a controlled substance listed in Schedule II is prohibited. However, an individual practitioner may issue multiple prescriptions authorizing the patient to receive a total of up to a 90-day supply of a Schedule II controlled substance, providing each prescription is issued for a legitimate medical purpose by an individual practitioner acting in the usual course of professional practice. The individual practitioner provides written instructions on each prescription (other than the first prescription, if the prescribing practitioner intends for that prescription to be filled immediately) indicating the earliest date on which a pharmacy may fill each prescription.
- h. Partial dispensing of controlled substances.** The Act does not prohibit the partial dispensing of controlled substances in Schedules III and IV, provided that each partial filling is recorded in the same manner as refills, the total quantity dispensed in all partial fillings does not exceed the total quantity prescribed, and no partial filling occurs after 6 months from the date of issuance of the prescription. Likewise, all partial fillings of a Schedule V prescription must not exceed the total quantity prescribed.
- (1) Partial dispensing of a Schedule II controlled substance.** The partial dispensing of a Schedule II prescription is allowed if the pharmacist is unable to supply the full quantity or the prescription is for a terminally ill patient or a patient in a long-term care facility (LTCF). Under no other circumstance may a Schedule II prescription be partially dispensed.
- (a) Inadequate supply.** In cases of an inadequate supply, the dispensing pharmacist must note on the face of the prescription the amount dispensed. The remaining balance of the Schedule II prescription must be dispensed within 72 hrs of the first partial filling. If, for any reason, the balance is not dispensed within the 72-hr period, the pharmacist must notify the prescribing practitioner of this fact. The pharmacist may not dispense any further amounts pursuant to this prescription beyond the 72-hr period.
- (b) Terminally ill and patients in LTCFs.** It is the pharmacist's responsibility to ensure that a patient has a medical diagnosis documenting a terminal illness or that the patient is in an LTCF. Before any partial dispensing, the pharmacist must record on the prescription whether the patient is "terminally ill" or an "LTCF patient." Any partial dispensing without one of these notations shall be deemed to be a dispensing in violation of the Act. The total amount of the Schedule II substance dispensed in all partial fillings must not exceed the total quantity prescribed. Schedule II prescriptions for a terminally ill patient or a patient in an LTCF are valid up to 60 days from the date of issuance of the prescription by the practitioner. All of the following information must be recorded, either manually on the back of the prescription or via computer (with similar capabilities required for computerized refill record keeping), when partially dispensing a Schedule II prescription for a terminally ill patient or a patient in an LTCF:
- (i) Date of the partial filling
  - (ii) Quantity of drug dispensed
  - (iii) Remaining quantity authorized to be dispensed
  - (iv) Identification of the dispensing pharmacist
- i. Transfer of refill information for a controlled substance prescription.** Refill information concerning Schedules III, IV, and V controlled substances may be transferred to another pharmacy only once (if allowed by state law). Pharmacies electronically sharing a real-time, online database (such as chain pharmacies) may transfer refill information for these controlled substances up to the maximum number of refills permitted by law and the prescriber's authorization. The communication must be made directly between two licensed pharmacists. Both the original prescription and the transferred prescription must be maintained for 2 years from the date of the last refill. Certain information must be recorded as follows:
- (1) The transferring pharmacist must:**
- (a) Write the word "void" on the face of the original prescription
  - (b) On the back of the prescription, record the name, address, and DEA registration number of the pharmacy to which it was transferred and the name of the pharmacist receiving the information
  - (c) Record the date of the transfer and the name of the transferring pharmacist

- (2) The **receiving pharmacist** must:
  - (a) Write the word “transfer” on the face of the transferred prescription
  - (b) Record all of the information required for any controlled substance prescription (see I.I.3), and include the following:
    - (i) Date of issuance of the original prescription
    - (ii) Original number of refills authorized on the original prescription
    - (iii) Date the prescription was initially dispensed
    - (iv) Number of valid refills remaining and the date of the last refill
    - (v) Pharmacy’s name, address, DEA registration number, and original prescription number from which the prescription information was transferred
    - (vi) Name of the transferring pharmacist
- J. **Dispensing of controlled substances to a patient without a prescription.** Controlled substances that are not prescription (or legend) drugs under federal law may be dispensed to a patient at retail without a prescription. These drugs do not have on the manufacturer’s label the federal statement: “Caution: Federal law prohibits dispensing without a prescription.” The substances may be dispensed without a prescription in accordance with the following:
  1. The dispensing must be made only by a licensed pharmacist. The actual cash transfer or delivery may be made by a nonpharmacist.
  2. Not more than 8 oz of any substance containing opium, 4 oz of any other controlled substance, 48 dosage units of any substance containing opium, or 24 dosage units of any other controlled substance may be dispensed to the same purchaser in any 48-hr period.
  3. The purchaser is at least 18 years old.
  4. Any purchaser not known to the pharmacist must furnish suitable identification.
  5. A bound record book must be maintained for 2 years from the date of the last entry. The following information must be recorded for each purchase:
    - a. Name and address of the purchaser
    - b. Name and quantity of controlled substance purchased
    - c. Date of each purchase
    - d. Name or initials of the pharmacist who dispensed the substance to the purchaser
  6. All dispensing of a controlled substance without a prescription must be done in good faith and not to evade the provisions of the Act.
- K. **Security considerations**
  1. **Controlled substance seals.** Manufacturers must package certain controlled substances in a container with a securely affixed seal to reveal any tampering. Every bottle, multiple-dose vial, or other commercial container of any controlled substance listed in Schedule II, or of any narcotic controlled substance listed in Schedule III or IV, must be packaged with such a seal.
  2. **Felony convictions.** No DEA registrant may employ an individual who has access to controlled substances if that individual had previously been convicted of a felony offense related to controlled substances.
  3. **Manufacturer’s label.** Every commercial container of a controlled substance must have on its label the symbol designating the Schedule in which the controlled substance is listed. The symbol must appear in the upper right corner of the label or be overprinted on the label.
- L. **Record maintenance.** All records required to be maintained under the Act must be kept by the registrant for 2 years. The records may be maintained at a central location (e.g., at a chain pharmacy’s regional office) after notifying the DEA. However, executed DEA 222 Forms (Copy 3), all controlled substance prescriptions, and all inventories must be maintained at the pharmacy, not centrally. All Schedule II controlled substance records must be maintained separately and readily retrievable from all other records.
- M. **DEA inspections.** Inspections by the DEA of any registered facility may be conducted only in a reasonable manner and during regular business hours. Inspection may be conducted after obtaining consent of the registrant or after the DEA has obtained an administrative warrant from a judge. An application for an administrative warrant must state with specificity the nature, extent, and authority to conduct the requested inspection. The scope of an administrative inspection extends to any records required under the Act, equipment and containers used in the handling of controlled substances, and the verification of compliance with any requirement of the Act. If records are removed from the registrant by the DEA, a receipt given to the registrant will list the items taken.

- N. Long-term-care facilities (LTCFs).** An LTCF is defined as a nursing home, retirement care, mental care, or other facility or institution that provides extended health care to resident patients. LTCFs are not normally registered with the DEA, although they often maintain controlled substances that are dispensed to a patient by prescription from a pharmacy. They are not required to be registered with the DEA because the controlled substance is dispensed to the ultimate user (the patient) and is not issued by or through the LTCF. When disposing of controlled substances, LTCFs must contact the nearest DEA Diversion Field Office for disposal instructions.
- 1. Emergency kits for LTCFs.** An LTCF may maintain controlled substances in emergency kits so long as state law specifically approves of such use and the state sets forth procedures that require the following:
    - a. Source of supply.** The LTCF must obtain controlled substances for the emergency kits from a DEA-registered hospital/clinic, pharmacy, or practitioner.
    - b. Security safeguards.** Access to each emergency kit in the LTCF must be restricted, and the type and quantity of controlled substances that may be placed in the emergency kit must be specifically limited.
    - c. Proper control, accountability, and record keeping.** The LTCF and the providing DEA-registered hospital/clinic, pharmacy, or practitioner must maintain complete and accurate records of the controlled substances placed in the emergency kit, including the disposition of these controlled substances, as well as take periodic physical inventories of the drugs.
    - d. Administration of controlled substances.** In emergency medical situations when medication is needed from the emergency kit, only LTCF personnel who are authorized by an individual practitioner can administer the controlled substances.
    - e. Prohibited activities.** Prohibited activities can result in the state revocation, denial, or suspension of having emergency kits containing controlled substances in an LTCF.
  - O. Violations under the Act.** Penalties for violations of the Federal Controlled Substances Act depend on the Schedule of controlled substance involved, the unlawful act, **and the knowledge and intent of the violator.** It will also depend on whether it is a first offense or a subsequent offense.
    - 1. Civil penalty.** Generally, each violation of the Act may subject an individual to a civil penalty (fine) of up to \$10,000. The government must prove that the violator was negligent with respect to compliance under the Act, as opposed to mere mistake or inadvertence.
    - 2. Imprisonment.** If an individual knowingly and intentionally violates the Act, he or she may be sentenced to a term of years, in addition to a civil penalty.

**II. FEDERAL FOOD, DRUG, AND COSMETIC ACT (FDCA).** In 1937, sulfanilamide elixir containing deadly diethylene glycol (automobile antifreeze) was manufactured without any safety data. There were numerous deaths associated with its use, which prompted the federal government to pass the 1938 FDCA. The FDCA requires that all new drug products intended for use as labeled by the manufacturer in the United States must be proven to the federal government to be safe and effective. Such proof is submitted to the Food and Drug Administration (FDA) by use of a New Drug Application (NDA).

- A. Definition.** Under the FDCA, the term *drug* is defined as including all of the following:
1. Articles recognized in the official *United States Pharmacopeia (USP)*, official *Homeopathic Pharmacopeia of the United States*, or official *National Formulary*, or any supplement to these
  2. Articles intended for use in the diagnosis, cure, mitigation, treatment, or prevention of disease in man or other animals
  3. Articles (other than food) intended to affect the structure or any function of the body of man or other animals
  4. Articles intended for use as a component of any article specified in 1, 2, or 3 as mentioned previously.
- B. Legend drugs.** Legend drugs are those medications that have on their label from the manufacturer the following federally required statement: “Rx only.” Such medications may be dispensed directly to the patient by means of a valid written or oral prescription from a practitioner or by a valid refill authorization of either. By law, these medications must bear a label with adequate directions for use, which can only be given by a licensed practitioner and, therefore, the requirement of a prescription.

A drug, intended for use by humans, is considered a legend drug (and has the aforementioned caution on its label) if any of the following apply:

1. Because of the drug's toxicity or other potential for a harmful effect, or its method of use, or collateral measures necessary to its use, it is **not safe** for use **except under the supervision** of a practitioner licensed by law to administer such drug.
  2. The drug is a **new drug** for which an approved NDA limits its use to the professional supervision of a practitioner licensed by law to administer such drug. A new drug is broadly defined as being one that generally is not recognized among experts as safe and effective for use under the conditions prescribed, recommended, or suggested in the labeling. It is also defined as being a drug that, as a result of investigations to determine its safety and effectiveness for use under such conditions, has become so recognized but that has not, other than in the investigations, been used to a material extent or for a material time under such conditions. Finally, a new drug may result from a change in the dosage form, labeling, indications, or any other change in a drug product that is already being marketed. The ultimate decision of whether a drug is a new drug lies with the FDA because of its expertise in resolving technical and scientific questions.
    - a. **NDA.** Every new drug marketed in the United States must be safe and effective for its intended use as labeled by the manufacturer. Proof of safety and effectiveness must be submitted to the FDA by the manufacturer via the NDA. When a new chemical entity (NCE) is identified by a manufacturer, the manufacturer must obtain an Investigational New Drug Application (IND) before conducting preclinical animal tests and clinical human investigations.
    - b. **IND.** Because an NCE has not yet been approved by the FDA as a safe and effective drug, a manufacturer is required to file an IND with the FDA. The IND allows a manufacturer to conduct research with the NCE and exempts the drug from certain prohibitions of the FDCA in order to facilitate clinical investigations; thus, INDs are sometimes referred to as an Investigational New Drug Exemption. Generally, clinical investigation of an NCE is divided into three phases, with each phase involving a greater number of human subjects.
      - (1) **Phase 1.** A phase 1 investigation is the initial introduction of an investigational new drug into humans to determine the metabolism, pharmacology, side effects, mechanism of action, and early evidence on effectiveness.
      - (2) **Phase 2.** A phase 2 investigation includes the well-controlled, closely monitored clinical studies in order to evaluate the effectiveness of the drug for a particular indication and to further determine side effects and risks.
      - (3) **Phase 3.** A phase 3 investigation includes expanded clinical trials to gather additional information concerning safety, effectiveness, and the overall benefit–risk relationship associated with the drug's use. This phase also includes gathering information to provide an adequate basis for physician labeling.
    - c. **Treatment INDs (or treatment protocols).** The FDA may allow a treatment IND, which allows a researcher (physician) to use an investigational drug as treatment in serious and life-threatening diseases where no comparable or satisfactory alternative drug or other therapy is available.
- C. **Over-the-counter (OTC) medications.** Certain medications may be dispensed OTC at retail distributors without a prescription. The federal government has determined that these medications may be safely and properly self-administered without the supervision of a practitioner licensed by law to administer (or prescribe) such a drug. Generally, these medications are not habit-forming and have a low toxicity or other potential for a harmful effect. These medications do not have the federal statement “**Rx only**” on their label (see II.B).
1. OTC preparations must have **adequate directions** for use on their label, and the product must comply with the applicable FDA monograph. The FDCA requires all drugs marketed in the United States to be generally recognized as safe and effective. As a result, it convened review panels to review OTC drug effectiveness and create monographs for each therapeutic class of OTC drugs. This review is referred to as the Drug Efficacy (or Effectiveness) Study Implementation (DESI). All OTC drugs must comply with the applicable drug monograph or be considered misbranded (see II.I) and subject to FDA regulatory action.
  2. OTC preparations must have the following information on its label:
    - a. Identity, in bold face, of the OTC product on the principal display panel
    - b. Adequate directions for use

- c. Ingredients (including inert or inactive ingredients) in the product
  - d. Net quantity of contents
  - e. Expiration date of the product
  - f. Lot number of the product
  - g. Name and place of business of the manufacturer, packer, or distributor
  - h. Disclosure of certain contents and the declaration of certain warnings, including habit-forming ingredients and warnings, pregnancy/nursing warnings, and aspirin warnings
3. **Prescription drug conversion to OTC.** A legend drug will convert to an OTC drug when the FDA finds that the prescription-only limitation is not necessary for the protection of the public health by reason of the drug's toxicity or other potential for harmful effect, the method of its use, or the collateral measures necessary to its use. The FDA must also find that the drug is safe and effective for use in self-medication as directed in proposed labeling.
4. **Miscellaneous regulations for OTCs.**
- a. **Ipecac syrup.** Although ipecac syrup can only be dispensed pursuant to a prescription, the FDA believes that it should be readily available OTC as an emergency treatment emetic for use in poisonings. The FDA allows the OTC sale of ipecac syrup in 1 fluid ounce containers so that it will be readily available in the household for emergency treatment of poisonings, under medical supervision, and that the drug be appropriately packaged and labeled for this purpose.
  - b. **Pregnancy-nursing warning.** All OTC drugs intended for systemic absorption must contain a warning that if the user is pregnant or nursing a baby, she should first seek the advice of a health professional before using the product. Exceptions to this labeling requirement exist when an OTC is intended to benefit the fetus or nursing infant, and for OTC drugs that are labeled exclusively for pediatric use.
  - c. **Aspirin warnings.** All OTC aspirin containing preparations must have a warning to keep out of children's reach and to contact a physician immediately in case of accidental overdose. Oral or rectal OTC aspirin containing preparations must also have a warning concerning Reye syndrome in children and teenagers.
  - d. **Chemicals and precursors.** It was discovered that combination drug products containing ephedrine, pseudoephedrine, or phenylpropanolamine are the precursor materials used by illegal methamphetamine laboratories. The Comprehensive Methamphetamine Control Act of 1996 requires all retail distributors of these OTC products to fulfill certain obligations. A retail distributor includes a grocery store, general merchandise store, a pharmacy, or any other entity or person who sells these items to customers for personal use. For regulated transactions, a retailer must maintain a record of these transactions for a period of 2 years, must obtain proof of identity from customers, and must report suspicious regulated sales immediately to the DEA. The record must be maintained separately from other records of controlled substances, and the DEA suggests that the record be made in a bound log book similar to the record kept for the sale of OTC controlled substances (see I.J). The following single transactions of these products in the amounts stated are considered to be "regulated transactions."
    - (1) **Phenylpropanolamine (PPA).** PPA is no longer in any OTC drug product.
    - (2) **Pseudoephedrine.** Sales of combination products containing more than 24 g of pseudoephedrine. Blister pack sales of these products exceeding 24 g are **not** regulated sales.
    - (3) **Ephedrine.** Sales of combination products containing more than 24 g of ephedrine **and all** single-entity ephedrine products regardless of the amount of ephedrine (more than 0 g).

#### D. Generic drugs

1. **Definition.** The *generic name* of a drug has been defined as its chemical name, a common name, or an official name used in an official compendium. A manufacturer seeking approval from the FDA for a drug that has already been proven to be safe and effective may file an Abbreviated New Drug Application (ANDA).
2. **ANDA.** A filing of an ANDA allows the approval of a drug for which exhaustive safety and efficacy studies have already been performed. A drug is considered to be the same as an approved drug when the two are identical in active ingredient(s), dosage form, strength, route of administration, indications, and conditions of use. Rigorous animal and human data to determine safety

and effectiveness are not required in the ANDA. However, information showing that the generic version of the drug is bioavailable and bioequivalent to the pioneer (original) drug is necessary. Such approved drugs are listed by the FDA in the “Approved Drug Products with Therapeutic Equivalence Evaluations,” commonly referred to as the FDA Orange Book (because it comes from the FDA in an orange binder).

- E. Proprietary drugs.** The *proprietary name* of a drug is the name given by the manufacturer to designate the drug’s source of manufacture and to differentiate it from the same or chemically similar drugs from other manufacturers. Another name for the proprietary name of a drug is its trade name.
- F. Established names for drugs.** The FDCA authorizes the commissioner of the FDA to designate an official name for any drug if he or she determines that such action is necessary or desirable in the interest of usefulness and simplicity. The FDCA also requires that a drug’s established name appear on the label and labeling of the drug. A drug’s *established name* is defined as follows:
1. It may be an **official name** designated by the commissioner of the FDA. For NCEs, the name should be simple and useful. In this regard, the FDA recognizes the United States Adopted Names Council (USAN) in deriving names for NCEs. The USAN name is considered to be an official name recognized in an official compendium. The FDA may use another name if the USAN or common or usual name is unduly complex, misleading, or is not useful for any other reason.
  2. If no official name has been designated for the drug and the drug is an article recognized in an official compendium, then the **official title** contained in the compendium may be the established name.
  3. If neither of the aforementioned two apply, then the **common or usual name** of the drug may be its established name.
- G. Dispensing a prescription drug.** A prescription drug may be dispensed only by a practitioner or by a pharmacist pursuant to a written or oral prescription of a practitioner, or a refill of either. The prescription label on the container dispensed to the patient must contain certain information, or it will be considered misbranded and dispensed in violation of the FDCA. This information is minimal under the FDCA and is usually supplemented by state laws, which require more information. So long as this information is in English, the dispensing pharmacist will be in compliance with the FDCA. If any of the required information is in another language, then all of the required information must be in that language. The prescription must also be packaged in a child-resistant container as required under the Poison Prevention Packaging Act (see III). The following information must appear on every prescription label:
1. Name and address of the pharmacy
  2. Serial number of the prescription
  3. Date the prescription is filled or the date of the prescription
  4. Name of the prescriber
  5. Name of the patient (if stated in the prescription)
  6. Directions for use and any cautionary statements contained in the prescription
- H. Drug recall.** The FDCA allows the FDA to initiate regulatory actions to ensure that unsafe, unfit, or ineffective products do not reach the market, or to promptly remove those products that do reach the marketplace. The enforcement actions that may be initiated include the release of information to the general public and/or professional groups; administrative actions and inspections; the institution of recall; or seizure, injunction, or criminal prosecution.
1. **Voluntary action of the manufacturer.** After several unsuccessful attempts by the FDA to receive court-ordered recalls, the FDA recognizes that recalls are voluntary actions of the manufacturers and distributors. As a result, a recall may be undertaken at any time, or upon request of the FDA. If the FDA is unsuccessful in persuading a company to recall a product, or when the FDA determines that a recall is or will be ineffective, it may seek a court order condemning the product and allowing the product’s seizure.
  2. **Drug recall classification.** After the FDA has evaluated the problem(s) associated with the product and after the degree of health hazard has been determined, the FDA will assign the recall one of the following classifications:
    - a. **Class I.** A situation in which there is a reasonable probability that the use of or exposure to a violative product will cause serious adverse health consequences or death

- e. If the drug is dispensed by a name that is recognized in an official compendium and it is either not packaged or not labeled in conformity with the official compendium
  - f. If the drug is determined by the federal government to be liable to deterioration and it is not packaged in a proper form and manner, and the label fails to bear a statement of proper precautions
  - g. If the drug is dispensed in a non-child-resistant container, when a child-resistant container is otherwise required (see III)
  - h. If the manufacturer fails to place on the label any of the following:
    - (1) Fact that certain drugs may be habit forming
    - (2) Name of each active ingredient
    - (3) Name and place of business of the manufacturer, packer, or distributor
  - i. If a pharmacist fails to place on a prescription container label any of the following:
    - (1) Name and address of the pharmacy
    - (2) Serial number of the prescription
    - (3) Date of filling the prescription or the date of the prescription
    - (4) Name of the prescriber
    - (5) Name of the patient
    - (6) Directions for use and any cautionary statements contained in the prescription
  - j. If an oral contraceptive is dispensed without the required patient package insert
  - k. If an intrauterine device that must be dispensed with a patient package insert is dispensed without the insert
  - l. If an estrogen product is dispensed without the required patient package insert
  - m. If a progestogen-containing product is dispensed without the required patient package insert
  - n. If a legend drug is dispensed (or refilled) without a prescription (or refill authorization) of a licensed practitioner, it is deemed to be misbranded by the dispensing pharmacist.
  - o. If the drug is an OTC drug and it is not packaged in tamper-resistant packaging or properly labeled in conformity with the tamper-resistant regulations (see IV)
  - p. If the drug is an OTC drug and it is not properly labeled in conformity with the labeling requirements of the FDCA
  - q. If the drug (or medical device) is an ophthalmic preparation offered or intended for ophthalmic use that is not sterile
3. **Violations under the Act.** Any misbranding or adulteration of a drug may subject the individual (e.g., a pharmacist) to imprisonment, a fine, or both. A pharmacy and pharmacist will be exempt from criminal sanctions in either of the following cases:
- a. **Certain cases of good faith.** When adulterated or misbranded products are received from a manufacturer or wholesaler in good faith by the pharmacy, the pharmacy may not be held responsible in certain situations. This exemption applies only if it is a first violation and, if requested, the pharmacy or pharmacist furnishes to the government the name and address of the person from whom the drug was received and copies of all documents pertaining to its delivery.
  - b. **Receipt of drug with a signed, written guaranty.** A pharmacy and pharmacist will be exempt from misbranding and adulteration violations when a signed, written guaranty is received from the wholesaler or manufacturer. The guaranty must contain the name and address of the person residing in the United States from whom the drug was received in good faith and a statement that the drug is not adulterated or misbranded.
4. **Seizures.** Any adulterated or misbranded drug will be subject to condemnation and seizure by the U.S. government after a hearing in any district court of the United States (or territory) with proper jurisdiction. A seizure may be done without a hearing if the federal government has probable cause to believe that the violation would be dangerous to health or that the labeling of the misbranded article is fraudulent or would be materially misleading to the injury or damage of the purchaser or consumer.
5. **Investigations and inspections**
- a. The U.S. Secretary of Health and Human Services has the authority to conduct examinations and inspections through federal employees and by officers and employees of any state, territory, or political subdivision duly commissioned by the U.S. Secretary of Health and Human Services as an officer of the U.S. Department of Health and Human Services.

particular warning or statement of benefits and risks associated with the use of the drug. For example, isotretinoin was approved for dispensing with an insert warning about serious fetal harm when administered to pregnant women.

#### L. Medication Guides

1. The “Medication Guide” bill was signed into law in August 1996. By 2006, 95% of patients receiving a new prescription were to receive written information in nontechnical language and in a uniform format. “Medication Guides” or “MedGuides” should not be confused with the patient leaflets generated by most pharmacy computer software programs. Patient leaflets are typically part of the pharmacy software package to process prescriptions and are written and updated by a source other than the manufacturer or FDA. The language of Medication Guides is approved by the FDA, whereas patient leaflets are not approved by the FDA. The manufacturers must make Medication Guides available electronically to pharmacies. The FDA Amendments Act of 2007 includes a “risk evaluation and mitigation strategy” (REMS), giving the FDA more power to require the sponsor or manufacturer of the drug to establish procedures to increase patient safety. One of the strategies is the distribution of Medication Guides.
2. The legislation has created significant confusion and controversy within the pharmacy and health care communities. Many pharmacists assume that the patient leaflet satisfies the Medication Guide requirement, but because the language was not approved by the FDA, the agency (FDA) says the two are not substitutable. It is not clear whether one manufacturer’s Medication Guide can be given to the patient when another manufacturer’s equivalent generic product is dispensed. Each manufacturer is to make the Medication Guides available to pharmacies. If a pharmacy gave the wrong manufacturer’s Medication Guide for a generic product, assuming the manufacturer’s name is on the document, technically this could be construed as a labeling violation. Professional pharmacy organizations and other interested parties (i.e., pharmaceutical manufacturers) are working with the FDA to clarify these requirements. On the FDA web site all current medication guides may be downloaded and printed. Individuals may also request to receive notice when new medication guides are available.

#### M. Prescription drug samples

1. An **amendment** to the FDCA (Prescription Drug Marketing Act) severely restricted the distribution of drug samples by manufacturers. Under the FDCA, no person may sell, purchase, or trade, or offer to sell, purchase, or trade any drug sample. Samples may only be distributed upon written request of a practitioner. Manufacturers must maintain records of every sample distribution for a period of 3 years. Pharmacies may not receive samples from a manufacturer except in certain situations in which a practitioner requests storage of his or her samples in the pharmacy.
2. **Importation under the FDCA.** The Prescription Drug Marketing Act prohibits the import of prescription drugs once exported. Importation is allowed after notification and approval of the FDA and in cases of an emergency.

**N. Medical devices.** An amendment to the FDCA in 1976 (Medical Device Amendments) required a device manufacturer to provide reasonable assurance of the safety and effectiveness of the device. The amendment required the FDA to categorize each device on the market in 1976 into one of three classes: Class I, Class II, or Class III, depending on each device’s safety and effectiveness. Generally, **Class I** devices are those that have a reasonable assurance of safety and effectiveness. **Class II** devices are those that do not have the reasonable assurance of safety and effectiveness, but there is sufficient information about the device to establish special controls to ensure its safety and effectiveness (and may be marketed with such controls). **Class III** devices are those for which information is not sufficient to provide reasonable assurance of their safety and effectiveness. Class III devices may be marketed only if they are proven to be substantially equivalent to a device on the market before 1976, by approval of a premarket application, or by reclassification into Class I or II.

1. **Medical device tracking.** Manufacturers of medical devices whose failure would be reasonably likely to have a serious adverse health consequence must track the device down the chain of distribution to the patient. Such tracking allows the manufacturer to take appropriate action with respect to recalls, defects, or other relevant information concerning the device. Every final distributor such as a pharmacy, hospital, or home health care company must report certain information to the manufacturer. Tracking information must be maintained by the manufacturer and distributor for the useful life of the device and be available for inspection by FDA personnel.

2. **Manufacturer's reports.** Every device manufacturer must report to the FDA information, when received or made aware of, that reasonably suggests that one of its marketed devices may have caused or contributed to a death or serious injury. Likewise, hospitals and other medical service facilities must provide reports on adverse reactions to, or malfunctioning of, medical devices.
3. **Adulteration and misbranding.** Medical devices may be adulterated or misbranded in the same way that drugs are adulterated or misbranded (see II.I).

**III. POISON PREVENTION PACKAGING ACT (PPPA).** The PPPA of 1970 requires that drugs for human use in an oral dosage form must be packaged for the consumer in special packaging. All such federal controlled substances and drugs dispensed pursuant to a prescription must be dispensed to the consumer in special packaging. **Special packaging**, referred to as **child-resistant** containers, is defined as a container that is designed to be significantly difficult for children younger than 5 years of age to gain access to within a reasonable time. The container must not be too difficult for normal adults (ones with no overt physical or mental handicaps) to use properly and does not include packaging that all such children cannot gain access within a reasonable time. The Consumer Products Safety Commission is responsible for interpreting, establishing rules and regulations for, and enforcing the provisions of the PPPA.

- A. Exceptions.** The following medications are exempt from the special packaging requirements:
1. Sublingual dosage forms of nitroglycerin; other dosage forms intended for oral administration, such as nitroglycerin sustained-release preparations, must be packaged in child-resistant containers
  2. Sublingual and chewable forms of isosorbide dinitrate in dosage strengths of 10 mg or less
  3. Erythromycin ethylsuccinate granules for oral suspension and oral suspensions in packages containing not more than 8 g of the equivalent of erythromycin
  4. Cyclically administered oral contraceptives in manufacturers' mnemonic (memory-aid) dispenser packages that rely solely on the activity of one or more progestogen or estrogen substances
  5. Anhydrous cholestyramine in powder form
  6. All unit-dose forms of potassium supplements, including individually wrapped effervescent tablets, unit-dose vials of liquid potassium, and powdered potassium in unit-dose packages, containing not more than 50 mEq of potassium per unit dose
  7. Sodium fluoride drug preparations, including liquid and tablet forms, containing not more than 264 mg of sodium fluoride per package and containing no other prescription medication
  8. Betamethasone tablets packaged in manufacturers' dispenser packages, containing not more than 12.6 mg betamethasone
  9. Pancrelipase preparations in tablet, capsule, or powder form and containing no other prescription medication
  10. Prednisone in tablet form, when dispensed in packages containing not more than 105 mg of the drug, and containing no other prescription medication
  11. Mebendazole in tablet form in packages containing not more than 600 mg of the drug and no other prescription medication
  12. Methylprednisolone in tablet form in packages containing not more than 84 mg of the drug and no other prescription medication
  13. Colestipol in powder form in packages containing not more than 5 g of the drug and no other prescription medication
  14. Erythromycin ethylsuccinate tablets in packages containing no more than the equivalent of 16 g erythromycin
  15. Conjugated estrogen tablets *USP*, when dispensed in mnemonic packages containing not more than 32 mg of the drug and no other prescription medication
  16. Norethindrone acetate tablets *USP*, when dispensed in mnemonic packages containing not more than 50 mg of the drug and no other prescription medication
  17. Medroxyprogesterone acetate tablets
- B. Requests for a non-child-resistant container.** A prescribing practitioner may make a request in the prescription that the medication be dispensed in a non-child-resistant container. A practitioner may not, however, make a blanket request that all prescriptions issued by him or her be dispensed in non-child-resistant containers. The purchaser, or patient, may also make a request that the medication be dispensed in a non-child-resistant container. The request of the purchaser, or patient, does not

(under the PPPA) have to be in writing. The purchaser, or patient, may make a blanket request that none of his or her medications be dispensed in a child-resistant container. A dispensing pharmacist may never make the decision to use non-child-resistant containers.

- C. **Reuse of child-resistant containers.** Reuse of child-resistant plastic containers are prohibited by regulation of the federal Consumer Products Safety Commission. However, the Commission has indicated that glass containers may be reused as long as a new safety closure is used.
- D. **Manufacturer's packaging.** Packaging from the manufacturer that is intended to be dispensed directly to the patient must be in child-resistant plastic packaging. Bulk packaging intended to be repackaged by the pharmacist for each prescription does not have to be in special packaging from the manufacturer. Unit packaging from the manufacturer that will be dispensed directly to the consumer, or patient, must comply with the child-resistant requirements of the PPPA (unless specifically exempted; see III.A).
- E. **Exemptions for easy access.** Special packaging is not required in cases where OTC medication needs to be readily available to the elderly or persons with disabilities. A manufacturer may supply a single size of a drug product in non-child-resistant packaging, as long as it also supplies the medication in packages that use the special packaging. Additionally, the package must be conspicuously labeled with the statement: "This package for households without young children." For those packages too small for this statement, the statement "Package not child-resistant" may be used.
- F. **Hospitals and institutions.** As long as the medication is administered by institutional personnel and is not directly dispensed to the consumer (patient), child-resistant containers are not required.
- G. **Household products and chemicals.** The special packaging requirements of the PPPA apply to household substances. *Household substance* is defined as "any substance which is customarily produced or distributed for sale for consumption or use, or customarily stored, by individuals in or about the household. . . ."
- H. **Miscellaneous products requiring special packaging.** The PPPA requires that certain household substances be distributed to the consumer in special packaging. Examples of these substances include furniture polish containing petroleum distillates, drain pipe cleaners, turpentine, paint solvents, and lighter fluid.

**IV. ANTI-TAMPERING ACT.** The U.S. Congress passed the Anti-Tampering Act in 1984 due to several deaths that occurred in the early 1980s from OTC medication capsules contaminated with cyanide.

- A. **Violations.** Unlawful acts involving a consumer product can be broken down into one of the following listed violations. The term *consumer product* includes any food, drug, device, or cosmetic, as well as any article, product, or commodity that is customarily used by individuals for purposes of personal care or to perform services ordinarily done within a household.
  - 1. **Tampering.** Any individual who tampers or attempts to tamper with any consumer product that affects interstate or foreign commerce, or its labeling or container, may be in violation of the statute. A violation occurs when the individual acts (or threatens to act) with reckless disregard for the risk that another person will be placed in danger of death or bodily injury. Any individual who taints any consumer product or causes its labeling or container to be materially false or misleading is in violation of the statute if done with intent to cause serious injury to the business of another.
  - 2. **False communications.** Knowingly communicating false information that a consumer product has been tainted may be a violation. If such tainting, had it occurred, would create a risk of death or bodily injury to another person, then the false communication is deemed a violation.
  - 3. **Conspiracy.** An agreement between two or more persons to do (or further) either of the aforementioned acts is considered a violation.
- B. **OTC tamper-resistant packaging.** Certain OTC products must be packaged, by FDA regulation, in tamper-resistant packaging. Examples include contact lens solutions and other ophthalmic solutions. A **tamper-resistant package** is one having one or more indicators or barriers to entry that, if breached or missing, can reasonably be expected to provide visible evidence to consumers that tampering has occurred. To reduce tampering, the package must have **one** of the following characteristics:
  - 1. Be distinctive by design so that the product cannot be duplicated by commonly available materials or processes or
  - 2. Use one or more indicators or barriers to entry that employ an identifying characteristic

- C. **OTC tamper-resistant labeling.** The OTC product must be labeled with a prominently placed statement alerting consumers to the specific tamper-resistant feature of the package. The statement must be placed so that it will be unaffected if the tamper-resistant feature is breached or missing.
- D. **Medical devices and cosmetics.** Certain medical devices and cosmetics must be packaged in tamper-resistant packaging. The packaging requirements are similar to the requirements outlined previously for OTC drug products.

## V. MAILING PRESCRIPTION MEDICATION

- A. All prescription medication, including controlled substances and narcotics in Schedules II to V, may be mailed from a physician, or pharmacist pursuant to a prescription, to the patient. Flammable substances (e.g., acetone) and alcoholic beverages may not be sent to a patient through the U.S. mail.
- B. The medication must be placed in a plain outer container or be securely overwrapped in plain paper. There must be no markings of any kind on the outside wrapper or container that would indicate the nature of the contents.

**VI. OMNIBUS BUDGET RECONCILIATION ACT OF 1990 (OBRA '90).** Under the Constitution of the United States, the federal government has no power or authority to directly regulate the practice of pharmacy. Such power rests with each state. The federal government can, however, indirectly regulate, or affect, the practice of pharmacy by attaching conditions of participation and reimbursement for federally funded programs.

- A. **Medicaid prescriptions.** With respect to prescriptions dispensed to Medicaid patients (paid in part by the federal government along with the state government), the federal government has attached certain conditions for reimbursement. Such conditions were deemed necessary to stem the always increasing cost of the Medicaid programs. It was believed that improved medication compliance by Medicaid recipients would, in the long run, reduce the cost of the programs by reducing subsequent hospitalizations and other subsequent utilization of health care. As a result, pharmacists are required to do the following in the course of dispensing a Medicaid prescription:
  - 1. Make a reasonable good-faith effort to obtain and maintain a history of the patient, including a medication history
  - 2. Conduct a review of every prescription for appropriateness and to screen for potential drug therapy problems
  - 3. Make an offer to counsel each Medicaid recipient concerning the drug (if the offer is accepted, the counseling must include the drug's proper administration, common adverse or severe side effects, techniques for self-monitoring, and proper storage)
- B. **Manufacturer's best price.** OBRA '90 requires manufacturers who wish to participate in the Medicaid program to offer the federal government their best price for prescription drugs. *Best price* is defined as the lowest price at which any purchaser is purchasing that drug product.

**VII. HEALTH INSURANCE PORTABILITY AND ACCOUNTABILITY ACT (HIPAA) OF 1996.** HIPAA is federal legislation that requires all health care providers, including pharmacies, to protect patient information from unauthorized use and disclosures. This is referred to as the Privacy Rule and was established as a result of the government's recognition that individually identifiable health information is readily available due to health care plans, health care clearinghouses, third-party billing practices, clinical research trials, and the transmission of health information in electronic form. Protected health information (PHI) must be confidentially maintained by a health care provider to prevent any unauthorized use or disclosure. Other covered entities, such as Organized Health Care Arrangements, health maintenance organizations (HMOs), and insurance plans, must also follow the Privacy Rule.

- A. **Definitions.** Under the Privacy Rule, certain terms have specific meanings.
  - 1. **"Covered entity"** means:
    - a. A health plan (e.g., group health insurance, Medicaid, Medicare)
    - b. A health care clearinghouse (e.g., billing service companies and companies that process health information received from another entity)

- c. A health care provider who transmits any health information in electronic form in connection with a transaction covered by HIPAA. *Health care* is defined as including the sale or dispensing of a drug, device, equipment, or other item in accordance with a prescription.
2. **“Individually identifiable health information”** is information created or received by a covered entity that relates to the past, present, or future physical or mental health or condition of an individual; the provision of health care to an individual; or any payment for any provision of any health care, **and** that identifies the individual **or** that provides a reasonable basis to identify the individual. The items listed in the following are deemed sufficient to identify an individual:
  - a. Name
  - b. Address, including all geographic subdivisions smaller than a state (e.g., street address, city, county, zip code)
  - c. Dates (except year), including birth dates, admission dates, discharge dates, dates of death
  - d. Telephone numbers
  - e. Fax numbers
  - f. E-mail addresses
  - g. Social Security numbers
  - h. Medical record numbers
  - i. Health plan beneficiary numbers
  - j. Account numbers
  - k. Certificate/license numbers
  - l. Vehicle identifiers and serial numbers, including license plate numbers
  - m. Device identifiers
  - n. Web universal resource locators (URLs)
  - o. Internet protocol (IP) address numbers
  - p. Biometric identifiers, including fingerprints and voice prints
  - q. Full face photographic images and any comparable images
  - r. Any other unique identifying number, characteristic, or code, except for codes assigned to reidentify information that has been de-identified
  - s. Names of any relative, employer, or household member of the individual
3. **“Protected health information” (PHI)** is all individually identifiable health information that is transmitted or maintained in any form or medium, electronically or otherwise.
4. **“Notice of privacy practices for protected health information.”** An individual has the right to adequate notice of the uses and disclosures of PHI that may be made by the covered entity, and of the individual’s rights and the covered entity’s legal duties with respect to PHI. Generally, the notice must contain information describing the individual’s rights under the Privacy Rule and the covered entity’s responsibilities.
  - a. **Header.** Every notice must contain the following statement as a header or be otherwise prominently displayed: “THIS NOTICE DESCRIBES HOW MEDICAL INFORMATION ABOUT YOU MAY BE USED AND DISCLOSED AND HOW YOU CAN GET ACCESS TO THIS INFORMATION. PLEASE REVIEW IT CAREFULLY.”
  - b. **Individual’s rights.** An individual has the right to request restrictions on certain uses and disclosures of PHI, the right to receive confidential communications of PHI by alternative means or at alternative locations, the right to inspect and copy his or her PHI, the right to amend his or her PHI, the right to receive an accounting of disclosures of PHI, and the right to obtain a paper copy of the notice from the covered entity.
  - c. **Covered entity’s responsibilities.** The notice must include a statement that the covered entity is required by law to maintain the privacy of PHI, a statement of its legal duties and privacy practices with respect to PHI, a statement that it must abide by the notice currently in effect, and a statement that it reserves the right to change the terms of its notice and how it will provide individuals with a revised notice.
  - d. **Miscellaneous contents of notice.** The notice must contain a statement that individuals may complain to the covered entity and to the U.S. Department of Health and Human Services if they believe their privacy rights have been violated. The notice must state a date on which it becomes effective. The effective date must be no later than the date of the first service delivery.

- e. **Posting of notice.** A pharmacy must post the notice in a clear and prominent location where it is reasonable to expect individuals to be able to read the notice.
  - f. **Written acknowledgment of notice.** Every covered entity must obtain a written acknowledgment of receipt of the notice by the individual. If one is not obtained, the covered entity must document its good-faith efforts to obtain the acknowledgment and the reason why it was not obtained.
  - g. **Exceptions for inmates.** A person incarcerated in or otherwise confined to a correctional institution does not have a right to notice under the Privacy Rule, and the notice requirements do not apply to a correctional institution that is a covered entity.
5. **“Authorization”** for a covered entity to use or disclose PHI: a patient must give written authorization before a covered entity, including pharmacies and pharmacists, may use or disclose PHI. **No patient consent or authorization** is necessary when PHI use and disclosure is for **treatment, payment, or health care operations**. This allows a health care provider to consult with other covered entities (i.e., other health care providers) to provide proper patient care without being unduly hindered by the Privacy Rule. For uses and disclosures that require an authorization, the **written authorization** must be written in plain language, and a **signed copy** must be provided to the individual. The signed authorization must be maintained by the covered entity for **6 years** from the date of its creation or the date when it was last in effect, whichever is later. The written authorization must at least contain the following core elements and statements:
- a. A description of the information to be used or disclosed that identifies the information in a specific and meaningful fashion.
  - b. The name or other specific identification of the person(s), or class of persons, authorized to make the requested use or disclosure.
  - c. The name or other specific identification of the person(s), or class of persons, to whom the covered entity may make the requested use or disclosure.
  - d. A description of each purpose of the requested use or disclosure.
  - e. An expiration date or an expiration event that relates to the individual or the purpose of the use or disclosure.
  - f. Signature of the individual and date. If signed by a personal representative, it must also include a description of such representative’s authority to act for the individual.
  - g. The written authorization must contain the following statements:
    - (1) The individual’s right to revoke the authorization in writing along with the exceptions to the right to revoke and a description of how the individual may revoke the authorization.
    - (2) The ability or inability to condition treatment, payment, enrollment, or eligibility for benefits on the authorization, by stating either that the covered entity cannot require authorization or that if the covered entity can require authorization, the consequences to the individual of his or her refusal to sign the authorization.
    - (3) The potential for the disclosed information to be redisclosed by the recipient and no longer be protected by the Privacy Rule.
6. **“Minimum necessary.”** When using or disclosing PHI or when requesting PHI from another covered entity, a covered entity must make reasonable efforts to limit PHI to the **minimum necessary** to accomplish the intended purpose of the use, disclosure, or request. The minimum necessary rule **does not apply** to disclosures or requests by a health care provider for treatment, uses or disclosures made pursuant to an authorization, and uses or disclosures that are required by law. “Required by law” means a mandate in a law that compels an entity to make a use or disclosure of PHI. It includes a covered entity’s compliance with state and federal laws and regulations that require the production of information; court orders and court-ordered warrants, subpoenas or summons issued by a court, a governmental or tribal inspector general, or an administrative body authorized to require the production of information and Medicare conditions of participation with respect to health care providers participating in the program.
7. **“Business associates.”** A business associate of a covered entity is a person or business that performs a function or activity on behalf of the covered entity, such as claims processing, billing, utilization review, quality assurance, etc., **and** that requires the use or disclosure of individually identifiable

health information. A business associate would also include persons who provide services to the covered entity, **and** the service involves disclosure of individually identifiable health information, such as legal, actuarial, accounting, consulting, data aggregation, management, administrative, accreditation, or financial services. **Excluded** from the definition of business associates are members of the workforce of the covered entity, and functions or services that do not require disclosure of individually identifiable health information.

- a. **Business associate contracts.** Every business associate must enter into an agreement with the covered entity to ensure compliance with the Privacy Rule. Generally, the agreement must establish the required uses and disclosures of PHI by the business associate and require the return or destruction of PHI at termination of the contract.
- B. **Additional responsibilities of covered entities.** Every covered entity must create policies and procedures for compliance with the Privacy Rule, must designate a privacy official responsible for creating such policies and procedures, must designate a contact person or office that is responsible for receiving complaints and that is able to provide further information about matters covered by the notice, and must train all members of its workforce with respect to the Privacy Rule. Every designation must be maintained by the covered entity for 6 years from the date it was last in effect. Lastly, every covered entity must have and apply appropriate sanctions against members of its workforce who fail to comply with the Privacy Rule.
- C. **State law privacy rules.** The federal Privacy Rule is intended as the minimum requirement for privacy standards. If a state law is more stringent, then a covered entity must follow that state's privacy standards. If a state privacy law is not as stringent, the federal Privacy Rule preempts any contrary state law and a covered entity must abide by the federal Privacy Rule.
- D. **Penalties for violation of the Privacy Rule.** Any person who violates the Privacy Rule may not be fined more than \$100 for each violation up to a total of \$25,000 per calendar year for all violations of an identical requirement. Additional penalties may be imposed for the following **wrongful disclosure** of individually identifiable health information:
  1. Wrongful obtainment or disclosure of PHI: fined not more than \$50,000, imprisoned not more than 1 year, or both.
  2. Wrongful obtainment or disclosure of PHI under false pretenses: fined not more than \$100,000, imprisoned not more than 5 years, or both.
  3. Wrongful obtainment or disclosure of PHI committed with intent to sell, transfer, or use same for commercial advantage, personal gain, or malicious harm: fined not more than \$250,000, imprisoned not more than 10 years, or both.

**VIII. OPIOID (NARCOTIC) ADDICTION TREATMENT PROGRAMS.** The Narcotic Addiction Treatment Program of 1974 and the Drug Addiction Treatment Act of 2000 amend the Federal Controlled Substances Act (CSA) in the treatment of drug addictions. The Narcotic Treatment Act (NTA) of 1974 required patients to begin treatment in a facility for “detoxification” and then later would receive treatment on an outpatient basis through a “maintenance” program. Facilities, physicians, and pharmacies serving in this program must have separate DEA registrations. The pharmacy for example is required to separate registrations based on detoxification, maintenance, and if the pharmacy provides compounding. There are multiple types of registrations: detoxification, maintenance, detoxification and maintenance, detoxification compounding, maintenance compounding, and detoxification and maintenance compounding. The major issue is using methadone (Schedule II) for the treatment of addictions and dividing the dosage (compounding) so patients are unaware of the tapering of the dosage.

The NTA of 1974 that established the narcotic treatment programs was the system for treating opioid addictions. The system was criticized for poor outcomes, being inflexible, and only serving a small percentage of patients, and in 2000, the Congress and the President signed into law a new regulation repealing FDA regulations and transferring the enforcement to the Substance Abuse and Mental Health Services Administration (SAMHSA). The name was changed from narcotic treatment programs to opioid treatment programs.

- A. **Opioid treatment programs.** The narcotic treatment programs until May of 2001 required patients to start treatment in an approved facility. The Congress, recognizing that this requirement created a substantial barrier, passed the **Drug Addiction Treatment Act (DATA)**.

This new law creates a way for office-based physicians to treat addicts on an outpatient basis. “Qualifying Physicians” may prescribe and dispense Schedule III, IV, and V opioids that have been approved by the FDA for maintenance or detoxification. Currently, buprenorphine sublingual tablets (Subutex) and buprenorphine-naloxone tablets (Suboxone) are the approved drugs for this purpose.

- B. **Qualifying Physicians.** “Qualifying Physicians” is defined in part as a physician board certified in addiction psychiatry or addiction medicine. The definition also defines “qualified” as a physician attending an 8-hr training in the treatment and management of opioid-dependent patients. Each qualifying physician may not treat more than 100 opioid-dependent patients. In order to prescribe to patients in this program, the physicians must obtain a special DEA number.
- C. **Methadone**
  - 1. Methadone is a Schedule II controlled substance and is approved by the FDA for the treatment of pain. The pharmacist may dispense and compound methadone prescriptions with the standard DEA registration.
  - 2. When methadone or any Schedule II drug is used for the detoxification and maintenance of narcotic addiction treatment, the practitioners must obtain a separate DEA registration as a narcotic treatment program and register with the SAMHSA of the Department of Health and Human Services (HHS).

**IX. FOOD AND DRUG ADMINISTRATIVE AMENDMENTS ACT (FDAAA) OF 2007.** This law was enacted in September of 2007 reauthorizing and amending many drug and device provisions that were to expire. The Act also provides new funding and more authority over drug safety. The FDAAA allows the FDA broader use of the fees generated by the Prescription Drug User Fee Act and increases the fees. The Act addresses some of the postmarket problems when approved products are removed because of safety concerns. The law gives the FDA expanded responsibilities and authority to regulate drug safety. The FDA can mandate label changes related to safety and require clinical trial reporting and postmarket studies to assess risks. The FDA under this new Act can require companies to implement risk evaluation and mitigation strategies (REMS).

The FDA under this Act has the authority to require Phase IV testing for any prescription drug. The FDA can require Phase IV studies to assess risks when the adverse event reporting or surveillance is not sufficient. The REMS provision gives the FDA the authority to require the sponsor or manufacturer of the drug to establish procedures and programs for patient safety. A REMS can require the distribution of Medication Guides, package inserts, or oral communication plan to health professions. If there is a high potential for risk, the REMS may require that the health care provider have special training or experience and/or the drug be only dispensed in specified settings and/or the patient be enrolled in a registry and agree to testing and monitoring.

The FDA did not have the authority until the passage of FDAAA to require manufacturers to modify the safety information or warnings in its labeling after the drug had been approved. The issue was that manufacturers had the label approved prior to marketing. Controversies arose between the FDA and manufacturer when new safety information was discovered and the FDA wanted the manufacturer to add more warnings on the label. FDAAA gives the FDA this power.

FDAAA requires that the FDA develop and maintain a Web site for patients and providers to have current access to labeling, safety information, and implemented REMS. Another safety provision is the development and maintenance of a surveillance system designed to detect early signs of medication risk and safety concerns.

**X. RYAN HAIGHT ONLINE PHARMACY CONSUMER PROTECTION ACT OF 2008.** The law amends the CSA by adding new requirements and criminal provisions to combat the proliferation of so-called rogue Internet sites. The Act applies to all Schedules of controlled substances. As of April 13, 2009, it is illegal to deliver, distribute, or dispense a controlled substance by means of the Internet unless the online pharmacy holds a modified DEA registration that authorizes this activity. The Act contains the definition of an online pharmacy, exemptions to registration, notification requirements to the DEA to provide online services, Web site, reporting and prescription requirements, and penalties for violations.

# Study Questions

**Directions:** Each of the numbered items or incomplete statements in this section is followed by answers or by completions of the statement. Select the **one** lettered answer or completion that is **best** in each case.

- You have been dispensing narcotics to a patient for several months for “back” pain. You are reasonably convinced that the drug is supporting an addiction. You call the physician and she tells you that she is using the narcotic for “back” pain. Select the best answer:
  - Refuse to refill the narcotic since it is not a “legitimate” medical purpose.
  - Fill the refill because pain is a “legitimate” medical purpose.
  - Call the medical board and report the physician.
  - Suggest OTC ibuprofen.
  - Give the patient part of the prescription.
- Which of the following narcotic drugs has been approved by the FDA for use in the treatment of narcotic addiction?
  - Morphine
  - Codeine
  - Methadone
  - Hydrocodone
  - None of the above
- For the U.S. government to place a drug into Schedule III, which of the following findings must be made concerning the drug?
  - The drug or other substance has a high potential for abuse.
  - Abuse of the drug or other substance may lead to limited physical dependence or psychological dependence relative to the drugs or other substances in Schedule IV.
  - The drug or other substance has no currently accepted medical use in treatment in the United States.
  - Abuse of the drug or other substance may lead to moderate or low physical dependence or high psychological dependence.
  - There is a lack of accepted safety for use of the drug or other substance under medical supervision.
- Under the Federal Controlled Substances Act, all of the following items must appear on a controlled substance prescription label *except* the
  - name, address, and DEA number of the pharmacy.
  - name of the patient.
  - name of the prescribing practitioner.
  - serial number assigned to the prescription.
  - date of the initial filling of the prescription.
- Under the Federal Controlled Substances Act, all of the following entities must register with the DEA *except*
  - prescribers of controlled substances.
  - pharmacists who dispense controlled substances.
  - distributors of controlled substances.
  - importers of controlled substances.
  - universities conducting instructional activities with controlled substances listed in Schedules II to V.
- Under the Federal Controlled Substances Act, which of the following statements concerning the emergency dispensing of a Schedule II controlled substance is true?
  - The practitioner who authorizes the oral prescription must, within 7 days, deliver a written prescription to the dispensing pharmacist.
  - The quantity prescribed and dispensed must be limited to the amount necessary to adequately treat the patient during the emergency period.
  - It is not reasonably possible for the practitioner to provide a written prescription to be presented to the person dispensing the controlled substance before the dispensing.
  - No appropriate alternative treatment is available, including administration of a controlled substance that is not in Schedule II.
  - All of the above statements are true.
- Under the Federal Controlled Substances Act, the crime transfer warning, “Caution: Federal law prohibits the transfer of this drug to any person other than the patient for whom it was prescribed,” must appear on the prescription container label of all controlled substances *except*
  - Schedule II controlled substances.
  - Schedule III controlled substances.
  - Schedule IV controlled substances.
  - Schedule V controlled substances.

8. Which of the following statements concerning drug recall classification is true?
- (A) A Class I recall is a situation in which the use of, or exposure to, a violative product is not likely to cause adverse health consequences.
  - (B) A Class I recall is a situation in which the use of, or exposure to, a violative product may cause temporary or medically reversible adverse health consequences or in which the probability of serious health consequences is remote.
  - (C) A Class I recall is a situation in which there is a reasonable probability that the use of, or exposure to, a violative product will cause serious adverse health consequences or death.
  - (D) A Class II recall is a situation in which the use of, or exposure to, a violative product is not likely to cause adverse health consequences.
  - (E) A Class III recall is a situation in which there is a reasonable probability that the use of, or exposure to, a violative product will cause serious adverse health consequences or death.
9. Under the Federal Food, Drug, and Cosmetic Act, all of the following statements are considered a misbranding of a drug *except* if
- (A) the labeling is false or misleading in any particular.
  - (B) an oral contraceptive is dispensed without the required patient package insert.
  - (C) the drug is an imitation of another drug, or if it is offered for sale under the name of another drug.
  - (D) the drug consists in whole or in part of any filthy, putrid, or decomposed substance.
10. All of the following oral medications are exempt from child-resistant packaging *except*
- (A) Anhydrous cholestyramine in powder form
  - (B) Nitroglycerin preparations in sustained-release form
  - (C) cyclically administered oral contraceptives in manufacturers' mnemonic (memory-aid) dispenser packages that rely solely on the activity of one or more progestogen or estrogen substances
  - (D) pancrelipase preparations in tablet, capsule, or powder form that contain no other prescription medication

## Answers and Explanations

---

1. **The answer is B** [see I.I.2].  
“Back Pain” is a “legitimate medical purpose” making the prescription valid and the best answer is to fill the order.
2. **The answer is C** [see VIII; VIII.A; I.I.2.c.(2)].  
Methadone is approved by the FDA for use in the treatment of narcotic addiction. Only a properly registered narcotic treatment program may dispense methadone for maintenance or detoxification treatment. Pharmacies that are not registered may only dispense methadone for severe pain.
3. **The answer is D** [see I.A.3].  
To place a drug into Schedule III, the U.S. government must make the following findings concerning the drug: (1) it has a potential for abuse less than the drugs or other substances in Schedules I and II; (2) it has a currently accepted medical use in treatment in the United States; and (3) abuse of the drug may lead to moderate or low physical dependence or high psychological dependence.
4. **The answer is A** [see I.I.8.c.(1)–(7)].  
A pharmacy's DEA number is not required to appear on the medication container label dispensed to the patient.
5. **The answer is B** [see I.B.2.a–k; I.B.9.d].  
Agents and employees of DEA registrants, such as pharmacists, are exempt from registering with the DEA. Pharmacies, not the individual pharmacists, must register with the DEA.
6. **The answer is E** [see I.I.4.a–b].  
Emergency dispensing of an oral Schedule II controlled substance prescription must be done in strict compliance with the law. Before dispensing such a prescription, the pharmacist must make the threshold determination that ALL three factors that define an emergency situation (see I.I.4.a) are present. If any one of the three factors is absent, the prescription is not for an emergency situation, and a written prescription must be presented to the pharmacist.

**7. The answer is D** [see I.I.8.c.(7)].

The federal crime transfer warning label is not required to appear on the prescription container label of Schedule V controlled substances.

**8. The answer is C** [see II.H.2.a-c].

A Class I recall is a situation in which there is a reasonable probability that the use of, or exposure to, a violative product will cause serious adverse health consequences or death.

**9. The answer is D** [see III.1, 2].

The Federal Food, Drug, and Cosmetic Act states that a drug is considered adulterated if it consists in whole or in part of any filthy, putrid, or decomposed substance. The terms misbranding and adulteration are often referred to in literature and case law as being the same or similar violations under the law. However, the Act sets forth specific instances of adulteration and specific instances of misbranding.

**10. The answer is B** [see III.A.1].

Only sublingual dosage forms of nitroglycerin are exempt from child-resistant packaging.

# Reviewing and Dispensing Prescription and Medication Orders

TODD A. BROWN

## I. DEFINITIONS

- A. **Prescriptions** are orders for medications, nondrug products, and services that are written by a licensed or midlevel practitioner who is authorized to prescribe (see Appendix A). Pharmacists are increasingly being given prescribing privileges by enactment of **collaborative drug therapy management (CDTM)** legislation. This allows pharmacists to modify existing medications and order new medication under established protocols or guidelines agreed on by the pharmacist and physician. Prescriptions may be written, presented orally (by telephone), or presented electronically (i.e., via fax or computer network) to the pharmacist. The requirements of the prescription form include security and tamper-resistant features that vary with state regulations. The prescription serves as a vehicle for communication from the prescriber to the pharmacist about the needs of the patient. The following information should be included:
1. **Patient information**, including full name and address
  2. **Date** on which the prescription was issued
  3. **Name and dosage form of the product**. The name can be any of the following:
    - a. Proprietary (brand)
    - b. Nonproprietary (generic)
    - c. Chemical
  4. **Product strength**. The strength of the product is not required if only one strength is commercially available or if the product contains a combination of active ingredients. It is advisable to include the strength to reduce the chance of misinterpretation.
  5. **Quantity to be dispensed**. This should include the amount and the units of measure (e.g., grams, ounces, tablets). If the amount is not specified, the directions should specify the dose to be taken and the duration of therapy so that the pharmacist can calculate the quantity required for the patient.
  6. **Directions for the pharmacist**. Directions may be required for:
    - a. Preparation (e.g., compounding)
    - b. Labeling (i.e., information to be put on the prescription label)
  7. **Directions for the patient**. These should include explicit instructions on the quantity, schedule, and duration for proper use. "As directed" should be avoided. If the directions vary, a minimum and maximum dose can be used.
  8. **Refill information**. If refill information is not supplied, it is generally assumed that no refills are authorized. "As needed" (pro re nata [prn]) refills are usually interpreted as allowing for refills for 1 year unless laws or regulations restrict the amount or period in which a prescription is valid.
  9. **Prescriber information**. This should include the name, office address, signature of the prescriber, the Drug Enforcement Administration (DEA) number (for controlled substances only), and the National Provider Identifier (NPI) number.

- B. Medication orders** are orders for medications by an individual authorized to prescribe and are intended for use by patients while in an institutional setting. They may be written, presented orally (by telephone), or presented electronically (i.e., via fax or computer network) to the pharmacist. The medication order generally includes the following:
1. **Patient information** (e.g., full name, identification number)
  2. **Date and time** the order was written
  3. **Name of the product.** The name can be any of the following:
    - a. Proprietary (brand)
    - b. Nonproprietary (generic)
    - c. Chemical
  4. **Product strength, dosage, and route of administration.** The strength of the product is not required if only one strength is commercially available or if the product contains a combination of active ingredients. It is advisable to include the strength to reduce the chance of misinterpretation. The pharmacist may decide the strength of the product dispensed after calculating the patient's dose. The dosage and route of administration should be included to reduce the chance of misinterpreting the order and to allow for correct administration to the patient.
  5. **Prescriber's signature.** If the order was taken verbally, the name of the person transcribing the order should be included.
  6. **Directions for the pharmacist.** These can be used for:
    - a. Preparation (e.g., compounding)
    - b. Labeling (i.e., information to be put on the label)
  7. **Instructions for administration,** including quantity, route of administration, schedule, and duration of use

## II. UNDERSTANDING THE PRESCRIPTION OR MEDICATION ORDER AND EVALUATING ITS APPROPRIATENESS

- A. Understanding the order.** A complete understanding of all information in a prescription or medication order is required. Each piece of information should be appropriate and consistent with the remaining information (i.e., the instructions for use should be appropriate for the medication being ordered). The pharmacist should determine the prescriber's intent by interpreting the following information:
1. The name and address of both the patient and the prescriber
  2. The patient's disease or condition requiring treatment
  3. The reason the order is indicated, relative to the medical need of the patient (e.g., an antibacterial for an infection)
  4. The name of the product, the quantity prescribed, and instructions for use
  5. All terminology, including units of measure (apothecary, metric, or English) and Latin abbreviations (see Appendix A for common abbreviations)
- B. Evaluating the appropriateness.** Complete information is required on the prescription or medication order to allow the pharmacist to evaluate the appropriateness. When the order is incomplete, the pharmacist must obtain the required information from either the patient or the prescriber. The following should be considered during an evaluation:
1. The patient's disease or condition requiring treatment
  2. The patient's allergies or hypersensitivities
  3. The pharmacological or biological action of the prescribed product
  4. The prescribed route of administration
  5. Whether the prescribed product might result in a drug–drug, drug–disease, or drug–food interaction
  6. Whether the dose, dosage form, and dosage regimen are safe and likely to meet the needs of the patient
  7. Whether the patient will have any difficulties adhering to the regimen and the potential impact on the therapeutic outcome desired
  8. Whether the total quantity of medication prescribed is sufficient to allow proper completion of a course of therapy

9. Whether a physical or chemical incompatibility might result (i.e., if the product requires extemporaneous compounding)
  10. Whether a licensed practitioner, acting in the course and scope of practice, issued the prescription in good faith, for a legitimate medical purpose
- C. **Discovering inappropriate prescriptions or medication orders.** Pharmacists are required to review medication profiles to ensure the appropriateness of prescribed medications. This is commonly called drug utilization review (DUR). Pharmacists should not fill or process prescriptions or medication orders that they have concerns with or that are considered inappropriate but, rather, should contact the prescriber. The process of calling a prescriber to discuss concerns identified during a DUR is commonly called **therapeutic intervention**.
1. When performing a therapeutic intervention, the following information should be provided:
    - a. A brief description of the problem
    - b. A reference source that documents the problem
    - c. A description of the clinical significance of the problem
    - d. A suggestion of a solution to the problem
  2. Documentation of the results of a therapeutic intervention is required if the prescription or medication order is changed. The name of the prescriber, date of communication, issues discussed, and resolution should be included in the documentation. This information should be kept for the same period as the prescription or medication order.
  3. If the pharmacist feels that, in his or her professional judgment, an order is inappropriate and could harm the patient, the pharmacist should not process the order. The pharmacist may also be required to explain the situation to the patient. If, after a therapeutic intervention, the pharmacist believes the order is still inappropriate, the guidelines of the institution and professional judgment should be followed.

**III. PROCESSING PRESCRIPTIONS AND MEDICATION ORDERS.** An environment that limits distractions and disruptions will assist in increasing the accuracy of this process. Automation and the use of pharmacy technicians allow the pharmacist to oversee these functions. The time saved allows the pharmacist greater time for patient-focused activities, such as counseling and patient education.

- A. The following information should be recorded on the prescription:
  1. The prescription number (for initial filling)
  2. The original date of filling
  3. The product and quantity dispensed
  4. The pharmacist's initials
- B. **Product selection.** Generic substitution statutes, as well as formulary and therapeutic substitution policies, might provide direction in product selection.
- C. **Product preparation** for use by the patient. The following might be necessary:
  1. Obtaining the proper amount of medication to be dispensed
  2. Reconstitution (the addition of liquid to make a solution or suspension)
  3. Extemporaneous compounding (see Chapter 4)
  4. Assembly of the medication delivery unit
- D. **Selection of the proper package or container** is required to ensure product stability, to promote patient compliance, and to comply with legal requirements.
- E. **Labeling the prescribed product**
  1. The **prescription label** typically contains the following information:
    - a. Name and address of the pharmacy
    - b. Patient's name
    - c. Original date of filling
    - d. Prescription number
    - e. Directions for use
    - f. Product's brand name or generic name and manufacturer
    - g. Product strength (if available in more than one strength)
    - h. Quantity of medication dispensed

- i. Prescriber's name
    - j. Expiration date of the medication
  2. **Unit-dose packages** contain one dose or one unit of medication. For a medication order that is dispensed in **unit-dose packages**, the label should identify the product's brand or generic name, strength, lot number, and expiration date.
  3. **Auxiliary and cautionary labels** ensure proper medication use, storage, and compliance and reinforce information provided during counseling.
  4. For medication in Schedules II to IV (see Chapter 63), a federal transfer warning is required.
- F. **Record keeping and confidentiality.** The pharmacist is required to maintain **prescription files and records** in accordance with standards of sound practice and statutory requirements. The implementation of the **Healthcare Insurance Portability and Accountability Act (HIPAA)** has put additional requirements on all health professionals who have access to health information (see Chapter 63). State prescription monitoring programs may require pharmacists to collect and provide information regarding the use of controlled substances. A **patient profile** contains patient demographic information and a complete chronological record of all medication use and services provided in the delivery of pharmaceutical care.
  1. The patient profile should contain the following **patient information**:
    - a. Patient's name
    - b. Patient's address (or room number in institutional settings)
    - c. Any known allergies, sensitivities, or history of idiosyncratic reactions to previous medications
    - d. Birth date (i.e., to assess the appropriateness of the dose)
    - e. Clinical condition(s) (to help assess the appropriateness of the medication and to prevent drug-disease interactions)
    - f. Weight (to assess the appropriateness of the dose)
    - g. Occupation (to detect conditions associated with a particular occupation and to help determine if the patient will be able to comply with the regimen)
    - h. Nonprescription medication use (to prevent drug interactions, to assess medication effectiveness, and to detect possible adverse effects)
  2. In addition, the patient profile should contain the following information from each prescription or medication order:
    - a. Name of the medication
    - b. Medication strength
    - c. Dosage form
    - d. Quantity dispensed
    - e. Directions for use
    - f. Prescription number
    - g. Dispensing date
    - h. Number of refills authorized and remaining
    - i. Prescriber's name
    - j. Pharmacist's initials

**IV. DISPENSING MEDICATION AND COUNSELING.** The dispensing of medication requires that the pharmacist verify that patients have the necessary knowledge and ability to adhere to the prescribed treatment. This will increase the likelihood of obtaining the desired outcomes.

- A. **Counseling patients.** The pharmacist should evaluate the patient's understanding of each medication and supply additional information when the patient's information is incorrect or insufficient. The pharmacist may need to advise patients regarding the proper dosage, appearance, and name of the medication. Information about the route of administration, instructions for use, duration of use, and the reason the product was prescribed may also be needed. In addition, the following topics might also be appropriate:
  1. **Special procedures.** As appropriate, the pharmacist should advise patients how to take the medication (e.g., on an empty stomach, with plenty of water) and on foods to avoid while taking the medication (e.g., alcoholic beverages, dairy products).

2. **Potential adverse effects.** The pharmacist should ensure that patients are aware of the possible adverse effects associated with a medication. Patients should understand the following:
    - a. The **frequency** of an adverse effect. This will help patients recognize common adverse effects and not be overly concerned with those that are rare.
    - b. The **severity** of an adverse effect. This will help patients focus on those adverse effects that are severe and not those that are inconsequential.
    - c. What action should be taken to **manage** or **minimize** the adverse effect. This will help patients deal with possible adverse effects in the appropriate manner.
  3. **Proper storage.** The pharmacist should counsel patients on how to store medications properly to ensure stability and potency.
  4. **Over-the-counter (OTC) products.** The pharmacist should instruct patients about the use of OTC products that may not be appropriate when taking a prescribed product.
- B. Counseling health professionals.** Health professionals (i.e., in an institutional setting) may administer medications to patients. In these cases, the pharmacist should ensure that the health professional has sufficient knowledge to administer the product. Information that health professionals would need include the following:
1. The choice of a particular product
  2. The proper dosage, dosage regimen, and route of administration
  3. The availability of commercially made products
  4. Potential adverse effects
  5. Drug interactions
  6. Physical incompatibilities
  7. Safe handling and disposal procedures
  8. Nutritional interactions or requirements
  9. Drug interference with laboratory tests

**V. PATIENT MONITORING.** The provision of pharmaceutical care requires a **pharmaceutical care plan**. Monitoring a patient's need for medication and the effect of the medication on the patient maximizes the effectiveness. Undesired outcomes associated with drug therapy are frequently called **drug therapy problems**.

- A. Pharmaceutical care plan.** To increase the frequency and benefits of desired outcomes, a pharmaceutical care plan should include the following:
1. **Assessment.** A review of the medical conditions and symptoms to determine the need for medication
  2. **Plan.** A decision of an appropriate drug therapy based on the assessment of the patient
  3. **Monitoring.** A review of the outcomes of drug therapy (i.e., goals and end points) to determine whether the patient is obtaining the desired outcomes
- B. Drug therapy problems** are evidence of less-than-optimal drug therapy. Detection requires an assessment of the need for a change in drug therapy. Possible problems include:
1. **Unnecessary drug therapy.** The medication cannot be associated with a medical condition or the presence of a condition in which nondrug therapy is more appropriate.
  2. **Wrong drug.** The drug is not indicated for the condition or is not delivering the desired outcomes, or a more effective drug is available.
  3. **Dose too low.** Incorrect dose, frequency, administration, or duration of therapy results in an insufficient dose of drug to the patient.
  4. **Adverse drug reaction.** An allergic reaction, drug interaction, or an undesirable effect occurs from a medication.
  5. **Dose too high.** Incorrect dose, frequency, or duration results in more medication than is required.
  6. **Inappropriate adherence.** The patient is not taking the optimal amount of medication owing to cost, administration difficulties, alternative health beliefs, or a lack of understanding of the need for the medication.
  7. **Need additional drug therapy.** Owing to an undertreated condition, synergism with concurrent drug therapy or prophylactic therapy is required.

# Study Questions

**Directions:** Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

- Medication orders differ from prescriptions in which of the following ways? They
  - are intended for ambulatory use.
  - contain only the generic name of the medication.
  - are intended for institutional use.
  - may be transmitted electronically.
  - contain the quantity of medication to be dispensed.
- If a therapeutic intervention is necessary, all of the following information should be communicated to the prescriber *except*
  - a declaration that “a mistake was made.”
  - a brief description of the problem.
  - a reference source that documents the problem.
  - an alternative or suggestion to resolve the problem.
  - a description of the clinical significance of the problem.
- The following information should be recorded on a prescription *except* the
  - prescription number.
  - date of filling.
  - expiration date.
  - product and quantity dispensed.
  - pharmacist’s initials.
- A prescription label usually contains all of the following *except* the
  - quantity dispensed.
  - lot number.
  - patient’s diagnosis.
  - expiration date.
  - prescriber’s name.
- Auxiliary and cautionary labels should be used for all of the following purposes *except* to
  - substitute for verbal consultation.
  - ensure proper usage.
  - inform of storage requirements.
  - comply with regulatory requirements.
  - warn against the concomitant use of certain drugs or foods.
- The following items are essential for a patient profile system *except*
  - the patient’s name.
  - the prescriber’s Drug Enforcement Administration (DEA) registration number.
  - the patient’s allergies.
  - the patient’s birth date.
  - instructions for medication use.
- The following are drug therapy problems *except*
  - an adverse effect from a medication.
  - symptoms caused by undertreatment.
  - a drug–drug interaction.
  - an undiagnosed condition.
  - an allergic reaction to a medication.

## Answers and Explanations

- The answer is C [see I.B].**

Medication orders are written for the care of inpatients. Both medication orders and prescriptions may contain the brand or generic name of the drug and may be transmitted electronically. Only prescriptions contain the quantity of medication to be dispensed.
- The answer is A [see II.C.1].**

Information provided to the prescriber during a therapeutic intervention should include a description of the problem, reference source, description of the clinical significance, and an alternative. Informing the prescriber that a mistake was made does not encourage cooperation and resolution of the problem.
- The answer is C [see III.A].**

The prescription number, date of filling, product and quantity dispensed, and pharmacist’s initials should be recorded on the prescription. The expiration date of the product is not required.
- The answer is C [see III.E.1].**

The quantity of medication dispensed, lot number, expiration date of the product, and prescriber’s name are usually included on the label. The patient’s diagnosis, although listed in the patient’s profile, is not included on the prescription label.

**5. The answer is A** [see III.E.3; IV.A.1].

Auxiliary and cautionary labels are an adjunct to, not a replacement for, verbal consultation. Appropriate uses for such labels include ensuring proper use, storage requirements, and compliance with statutory requirements, and warning against food and drug interactions.

**6. The answer is B** [see III.F.1–2].

The patient's name is required to identify each patient. Often, the address or room number is required to identify patients with similar names. The patient's allergies, birth date, and instructions for use are required to prevent drug allergies and to assess the appropriateness of the prescription or medication order.

**7. The answer is D** [see V.B].

Adverse effects, undertreated conditions, allergic reactions, and drug–drug interactions are all drug therapy problems. An undiagnosed condition may lead to a drug-related problem once diagnosed; however, diagnosis is required before the need for medication can be assessed.

# Common Prescription Drugs and Over-the-Counter Products

## TOP OVER-THE-COUNTER (OTC) DRUGS\*

	Generic Name	Trade Name	Drug Use
1	Docosanol	Abreva®	Cold sore medication
2	Ibuprofen and pseudoephedrine HCl	Advil Cold & Sinus®	Allergy and cold relief
3	Ibuprofen	Advil®	Analgesic
4	Oxymetazoline HCl	Afrin®	Nasal decongestant
5	Naproxen sodium	Aleve®	Analgesic
6	Orlistat	alli®	Weight management
7	Benzocaine, phenol	Anbesol®	Oral cavity analgesic
8	Phenazopyridine hydrochloride	Azo Standard®	UTI analgesic
9	Acetylsalicylic acid (ASA, aspirin), diphenhydramine, caffeine, calcium, phytosterols	Bayer® Aspirin	Analgesic
10	Diphenhydramine HCl, phenylephrine HCl	Benadryl® Oral	Allergy and cold relief
11	Diphenhydramine HCl, zinc acetate or camphor	Benadryl® Topical	Topical antipruritic
12	Methyl salicylate, menthol, and camphor	BENGAY®	Topical analgesic
13	Meclizine hydrochloride, cyclizine hydrochloride	Bonine®	Motion sickness medication
14	Acetylsalicylic acid (ASA, aspirin) with buffers	Bufferin®	Analgesic
15	Capsaicin	Capzasin-P	Topical analgesic
16	Menthol, camphor, alum, salicylic acid	Carmex® Lip Balm	Cold sore medication
17	Benzocaine, menthol, dextromethorphan	Cepacol®	Oral cavity analgesic
18	Benzocaine and menthol or phenol	Chloraseptic®	Oral cavity analgesic
19	Calcium citrate	Citracal®	Essential mineral
20	Loratadine and pseudoephedrine sulfate	Claritin-D®	Allergy and cold relief
21	Loratadine	Claritin®	Allergy and cold relief
22	Docusate sodium	Colace®	Stool softener
23	Zincum gluconicum	COLD-EEZE®	Cold relief
24	Salicylic acid	Compound W®	Keratolytic
25	Hydrocortisone	Cortaid®	Topical antipruritic
26	Acetaminophen, dextromethorphan HBr, phenylephrine HCl	DayQuil®	Allergy and cold relief
27	Carbamide peroxide solution	Debrox®	Ear wax removal aid
28	Dextromethorphan polistirex	Delsym®	Cough suppressant
29	Zinc oxide	Desitin®	Skin protectant
30	Brompheniramine maleate, phenylephrine hydrochloride, dextromethorphan hydrobromide, loratadine	Dimetapp®	Allergy and cold relief
31	Dimenhydrinate or meclizine HCl	Dramamine®	Motion sickness medication
32	Bisacodyl	Dulcolax®	Laxative
33		e.p.t.®	Pregnancy test
34	Acetylsalicylic acid (aspirin, ASA)	Ecotrin	Analgesic
35	Phosphorated carbohydrates	Emetrol®	Antiemetic

# Prescription Dispensing Information and Metrology

## Prescriptions

### PARTS OF THE PRESCRIPTION

A prescription is an order for medication for use by a patient that is issued by a physician, dentist, veterinarian, or other licensed practitioner who is authorized to prescribe medication or by their agent via a collaborative practice agreement. A prescription is usually written on a single sheet of paper that is commonly imprinted with the prescriber's name, address, and telephone number. A medication order is similar to a prescription, but it is written on the patient chart and intended for use by a patient in an institutional setting.

All prescriptions should contain accurate and appropriate information about the patient and the medication that is being prescribed. In addition, a prescription order for a **controlled substance** must contain the following information:

1. Date of issue
2. Full name and address of the patient
3. Drug name, strength, dosage form, and quantity prescribed
4. Directions for use
5. Name, address, and Drug Enforcement Agency (DEA) number of the prescriber
6. Signature of the prescriber

A written prescription order is required for substances listed in **Schedule II**. Prescriptions for controlled substances listed in **Schedule II** are **never** refillable. Any other prescription that has no indication of refills is not refillable.

Prescriptions for medications that are listed in Schedules III, IV, and V may be issued either in writing or orally to the pharmacist. If authorized by the prescriber, these prescriptions may be refilled up to five times within 6 months of the date of issue. If the prescriber wishes the patient to continue to take the medication after 6 months or five refills, a new prescription order is required.

### THE PRESCRIPTION LABEL

In addition to the name of the patient, the pharmacy, and the prescriber, the prescription label should accurately identify the medication and provide directions for its use.

The label for a prescription order for a controlled substance must contain the following information:

1. Name and address of the pharmacy
2. Serial number assigned to the prescription by the pharmacy
3. Date of the initial filling
4. Name of the patient
5. Name of the prescriber
6. Directions for use
7. Cautionary statements as required by law\*

### AUXILIARY LABELS

Auxiliary, or cautionary, labels provide additional important information about the proper use of the medication. Examples include “Shake Well” for suspensions or emulsions; “For External Use Only” for topical lotions, solutions, or creams; and “May Cause Drowsiness” for medications that depress the central nervous system. The information contained on auxiliary labels should be brought to the attention of the patient when the medication is dispensed. The pharmacist should place only appropriate auxiliary labels on the prescription container because too many labels may confuse the patient.

### BEFORE DISPENSING THE PRESCRIPTION

**Double-check the accuracy of the prescription.**

**Provide undivided attention when filling the prescription.**

1. Check the patient information (e.g., name, address, date of birth, telephone number).
2. Check the patient profile (e.g., allergies, medical conditions, other drugs, including over-the-counter medications).
3. Check the drug (e.g., correct drug name, correct spelling, appropriate drug for the patient's condition), and verify that there are no known drug interactions. **Always verify**

---

\*The label of any drug that is listed as a controlled substance in Schedule II, III, or IV of the Controlled Substances Act must contain the following warning: **CAUTION: Federal law prohibits the transfer of this drug to any person other than the patient for whom it was prescribed.**

**the name of the drug. Beware of drug names that look alike (see table).**

4. Check the dosage, including the drug strength, the dosage form (e.g., capsule, liquid, modified release), the individual dose, the total daily dose, the duration of treatment, and the units (e.g., mg, mL, tsp, tbsp).
5. Check the label. Compare the drug dispensed with the prescription. Verify the National Drug Code (NDC) number. Ensure that the information is accurate, that the patient directions are accurate and easily understood, and that the auxiliary labels are appropriate.
6. **Provide patient counseling. Be sure that the patient fully understands the drug treatment as well as any precautions.**

#### EXAMPLES OF DRUGS WITH SIMILAR NAMES

Brand name	Celebrex	Cerebyx	Celexa
Generic name	Celecoxib capsules	Fosphenytoin sodium injection	Citalopram HCl
Manufacturer	Searle	Parke-Davis	Forest
Indication	Osteoarthritis and rheumatoid arthritis	Prevention and treatment of seizures	Major depression

### Dangerous or Confusing Abbreviations

Numerous common abbreviations and symbols have been associated with errors. Detailed lists of these can be found at the websites of the Institute for Safe Medication Practices (ISMP) and Joint Commission for the Accreditation of Healthcare Organizations (JCAHO) at :

<http://www.ismp.org/Tools/abbreviationslist.pdf>.

[http://www.jcaho.org/accredited+organizations/patient+safety/06\\_dnu\\_list.pdf](http://www.jcaho.org/accredited+organizations/patient+safety/06_dnu_list.pdf).

The JCAHO has created a “Do Not Use” list of abbreviations that its accredited organizations should not allow to be used.

- **“U” or “IU” for units:** the “U” has been misinterpreted as various numbers such as zero, four; serious harm has occurred with insulin and heparin as a result of confusion. For example, a patient received 66 units of insulin instead of 6 units. The order was written for “6u” of regular insulin but was misinterpreted. The word “units” should be written out in full.

- **“QD, Q.D, qd, q.d.”:** common abbreviations for daily have been misinterpreted as “QID” or “qid” and overdoses have occurred. “Daily” should be written out in full.
- **“Q.O.D, QOD, qod”:** common abbreviations for every other day have been misinterpreted as QID (four times daily). This should be written out completely as “every other day.”
- **Trailing zero:** when a dose is ordered and followed with a decimal point and a zero, such as 2.0 mg or 25.0 mg, errors can occur. The decimal point may be missed and an overdose can occur. For example, Warfarin 2.0 mg may be misinterpreted as 20 mg. Trailing zeros should be avoided and the dose written without the additional zero, for example Warfarin 2 mg rather than 2.0 mg.
- **Lack of leading zero:** a drug’s dose may be less than 1 mg, such as Digoxin. Often the dose may be written without a leading zero, such as Digoxin .25 mg, rather than as Digoxin 0.25 mg. Errors have occurred because the decimal point is missed. For example, Warfarin .5 mg may be interpreted as Warfarin 5 mg. Leading zeroes should be included, so the dose is written as “Digoxin 0.25 mg or Warfarin 0.5 mg.”
- **MS, MSO<sub>4</sub>, MgSO<sub>4</sub>:** Abbreviations for morphine sulfate (MS, MSO<sub>4</sub>) have been confused with Magnesium sulfate (MgSO<sub>4</sub>). It is recommend to write out each name in full rather than using abbreviations: morphine sulfate or magnesium sulfate.

In addition to the above abbreviations, there are numerous other hazardous symbols and abbreviations which should be reviewed with caution when used on prescriptions. Examples include:

- **“cc”:** Often used instead of “mL.” This has been misinterpreted as a “0” (zero). Use “mL.”
- **“μg”:** Used for “micrograms,” for example, Levothyroxine 250 μg. daily. The symbol has been mistaken for “mg.” and overdoses have occurred. Best to use “mcg.” Or write out “micrograms.”
- **“<” or “>”:** Symbols for “less than” (<) or “greater than” (>) have been mistaken for each other or misinterpreted as numbers. Best to write out as “less than” or “greater than.”
- **“HCT”:** An abbreviation for “hydrocortisone” has been misinterpreted as “hydrochlorothiazide.” Best to write name out completely.
- **“HCl”:** An abbreviation for “hydrochloric acid” has been misinterpreted as “KCl” (potassium chloride). Best to write out name completely.

## COMMON ABBREVIATIONS

Considerable variation occurs in the use of capitalization, italicization, and punctuation in abbreviations. The following

list shows the abbreviations that are most often encountered by pharmacists.

<b>A, aa., or aa</b>	of each	<b>lb.</b>	pound
<b>a.c.</b>	before meals	$\mu$	Greek mu
<b>ad</b>	to, up to	<b>M</b>	mix
<b>a.d.</b>	right ear	<b>m<sup>2</sup> or M<sup>2</sup></b>	square meter
<b>ad lib.</b>	at pleasure, freely	<b>mcg, mcg., or <math>\mu</math>g</b>	microgram
<b>a.m.</b>	morning	<b>mEq</b>	milliequivalent
<b>amp.</b>	ampule	<b>mg or mg.</b>	milligram
<b>ante</b>	before	<b>ml or mL</b>	milliliter
<b>aq.</b>	water	$\mu$ l or $\mu$ L	microliter
<b>a.s.</b>	left ear	$\mathcal{R}$	minim
<b>asa</b>	aspirin	<b>N&amp;V</b>	nausea and vomiting
<b>a.u.</b>	each ear, both ears	<b>Na</b>	sodium
<b>b.i.d.</b>	twice a day	<b>N.F.</b>	National Formulary
<b>BP</b>	British Pharmacopoeia	<b>No.</b>	number
<b>BSA</b>	body surface area	<b>noct.</b>	night, in the night
<b>c. or c</b>	with	<b>non rep.</b>	do not repeat
<b>cap. or caps.</b>	capsule	<b>NPO</b>	nothing by mouth
<b>cp</b>	chest pain	<b>N.S., NS, or N/S</b>	normal saline
<b>D.A.W.</b>	dispense as written	<b>1/2 NS</b>	half-strength normal saline
<b>cc or cc.</b>	cubic centimeter	<b>O</b>	pint
<b>comp.</b>	compound, compounded	<b>o.d.</b>	right eye, every day
<b>dil.</b>	dilute	<b>o.l. or o.s.</b>	left eye
<b>D.C., dc, or disc.</b>	discontinue	<b>OTC</b>	over the counter
<b>disp.</b>	dispense	<b>o.u.</b>	each eye, both eyes
<b>div.</b>	divide, to be divided	<b>oz.</b>	ounce
<b>dl or dL</b>	deciliter	<b>p.c.</b>	after meals
<b>d.t.d.</b>	give of such doses	<b>PDR</b>	<i>Physicians' Desk Reference</i>
<b>DW</b>	distilled water	<b>p.m.</b>	afternoon, evening
<b>D5W</b>	dextrose 5% in water	<b>p.o.</b>	by mouth
<b>elix.</b>	elixir	<b>Ppt</b>	precipitated
<b>e.m.p.</b>	as directed	<b>pr</b>	for the rectum
<b>et</b>	and	<b>prn or p.r.n.</b>	as needed
<b>ex aq.</b>	in water	<b>pt.</b>	pint
<b>fl or fld</b>	fluid	<b>pulv.</b>	powder
<b>fl oz</b>	fluid ounce	<b>pv</b>	for vaginal use
<b>ft.</b>	make	<b>q.</b>	every
<b>g or Gm</b>	gram	<b>q.d.</b>	every day
<b>gal.</b>	gallon	<b>q.h.</b>	every hour
<b>GI</b>	gastrointestinal	<b>q. 4 hr.</b>	every four hours
<b>gr or gr.</b>	grain	<b>q.i.d.</b>	four times a day
<b>gtt or gtt.</b>	drop, drops	<b>q.o.d.</b>	every other day
<b>H</b>	hypodermic	<b>q.s.</b>	a sufficient quantity
<b>h. or hr.</b>	hour	<b>q.s. ad</b>	a sufficient quantity to make
<b>h.s.</b>	at bedtime	<b>R</b>	rectal
<b>IM</b>	intramuscular	<b>R.L. or R/L</b>	Ringer's lactate
<b>inj.</b>	injection	$\mathcal{R}$	prescription
<b>IV</b>	intravenous	<b>s. or s</b>	without
<b>IVP</b>	intravenous push	<b>Sig.</b>	write on label
<b>IVPB</b>	intravenous piggyback	<b>sol.</b>	solution
<b>K</b>	potassium	<b>S.O.B.</b>	shortness of breath
<b>l or L</b>	liter	<b>s.o.s.</b>	if there is need (once only)

<b>ss. or ss</b>	one-half	<b>t.i.d.</b>	three times a day
<b>stat.</b>	immediately	<b>tr. or tinct.</b>	tincture
<b>subc, subq, or s.c.</b>	subcutaneously	<b>tsp. or t.</b>	teaspoonful
<b>sup. or supp</b>	suppository	<b>TT</b>	tablet triturates
<b>susp.</b>	suspension	<b>U or u.</b>	unit
<b>syr.</b>	syrup	<b>u.d. or ut dict.</b>	as directed
<b>tab.</b>	tablet	<b>ung.</b>	ointment
<b>tal.</b>	such, such a one	<b>U.S.P. or USP</b>	United States Pharmacopoeia
<b>tal. dos.</b>	such doses	<b>w/v</b>	weight/volume
<b>tbsp. or T</b>	tablespoonful		

## Metrology

### THE METRIC, APOTHECARY, AND AVOIRDUPOIS SYSTEMS

#### Metric system

##### 1. Basic units

Mass = g or gram

Length = m or meter

Volume = L or liter

1 cc (cubic centimeter) of water is approximately equal to 1 mL and weighs 1 g.

##### 2. Prefixes

kilo-	$10^3$ , or 1000 times the basic unit
hekto-	$10^2$ , or 100 times the basic unit
deka-	$10^1$ , or 10 times the basic unit
deci-	$10^{-1}$ , or 0.1 times the basic unit
centi-	$10^{-2}$ , or 0.01 times the basic unit
milli-	$10^{-3}$ , or 0.001 times the basic unit
micro-	$10^{-6}$ , or one-millionth of the basic unit
nano-	$10^{-9}$ , or one-billionth of the basic unit
pico-	$10^{-12}$ , or one-trillionth of the basic unit

Examples of these prefixes include milligram (mg), which equals one-thousandth of a gram, and deciliter (dL), which equals 100 mL, or 0.1 L.

#### Apothecary system

##### 1. Volume (fluids or liquid)

60 minims (℥) = 1 fluidrachm or fluidram (f ℥)  
or (ʒ)

8 fluidrachms (480 minims) = 1 fluid ounce (f ʒ or ʒ)

16 fluid ounces = 1 pint (pt or 0)

2 pints (32 fluid ounces) = 1 quart (qt)

4 quarts (8 pints) = 1 gallon (gal or C)

##### 2. Mass (weight)

20 grains (gr) = 1 scruple (ʒ)

3 scruples (60 grains) = 1 drachm or dram (ʒ)

8 drachms (480 grains) = 1 ounce (ʒ)

12 ounces (5760 grains) = 1 pound (lb)

#### Avoirdupois system

##### 1. Volume

1 fluidrachm = 60 min.

1 fluid ounce = 8 fl. dr.  
= 480 min.

1 pint = 16 fl. oz.  
= 7680 min.

1 quart = 2 pt.  
= 32 fl. oz.

1 gallon = 4 qt.  
= 128 fl. oz.

##### 2. Mass (weight)

The grain is common to both the apothecary and the avoirdupois systems.

437.5 grains (gr) = 1 ounce (oz)

16 ounces (7000 grains) = 1 pound (lb)

## CONVERSION

### Exact equivalents

Exact equivalents are used for the conversion of specific quantities in pharmaceutical formulas and prescription compounding.

##### 1. Length

1 meter (m) = 39.37 in.

1 inch (in) = 2.54 cm.

##### 2. Volume

1 ml = 16.23 minims (℥)

1 ℥ = 0.06 mL

1 f ʒ = 3.69 mL

1 f ʒ = 29.57 mL

1 pt = 473 mL

1 gal (U.S.) = 3785 mL

**3. Mass**

$$1 \text{ g} = 15.432 \text{ gr}$$

$$1 \text{ kg} = 2.20 \text{ lb (avoir.)}$$

$$1 \text{ gr} = 0.065 \text{ g or } 65 \text{ mg}$$

$$1 \text{ oz (avoir.)} = 28.35 \text{ g}$$

$$1 \text{ } \frac{3}{4} \text{ (apoth.)} = 31.1 \text{ g}$$

$$1 \text{ lb (avoir.)} = 454 \text{ g}$$

$$1 \text{ lb (apoth.)} = 373.2 \text{ g}$$

**4. Other equivalents**

$$1 \text{ oz (avoir.)} = 437.5 \text{ gr}$$

$$1 \text{ } \frac{3}{4} \text{ (apoth.)} = 480 \text{ gr}$$

$$1 \text{ gal (U.S.)} = 128 \text{ fl } \frac{3}{4}$$

$$1 \text{ fl } \frac{3}{4} \text{ (water)} = 455 \text{ gr}$$

$$1 \text{ gr (apoth.)} = 1 \text{ gr (avoir.)}$$

**Approximate equivalents**

Physicians may use approximate equivalents to prescribe the dose quantities using the metric and apothecary systems of weights and measures, respectively. Household units are often used to inform the patient of the size of the dose. In view of the almost universal practice of using an ordinary household teaspoon to administer medication, a teaspoon may be considered 5 mL. However, when accurate measurement of a liquid dose is required, the USP recommends the use of a calibrated oral syringe or dropper.

$$1 \text{ fluid dram} = 1 \text{ teaspoonful} \\ = 5 \text{ mL}$$

$$4 \text{ fluid ounces} = 120 \text{ mL}$$

$$8 \text{ fluid ounces} = 1 \text{ cup} \\ = 240 \text{ mL}$$

$$1 \text{ grain} = 65 \text{ mg}$$

$$1 \text{ kg} = 2.2 \text{ pounds (lb)}$$

# Reference Charts For Patient Counseling

## DRUGS THAT SHOULD NOT BE CRUSHED

Listed below are various slow-release as well as enteric-coated products that should not be crushed or chewed. Slow-release (sr) represents products that are controlled-release, extended-release, long-acting, or timed-release. Enteric-coated (ec) represents products that are delayed-release.

In general, capsules containing slow-release or enteric-coated particles may be opened and their contents administered

on a spoonful of soft food. Instruct patients not to chew the particles, though. (Patients should, in fact, be discouraged from chewing any medication unless it is specifically formulated for that purpose.)

This list should not be considered all-inclusive. Generic and alternate brands of some products may exist. Tablets intended for sublingual or buccal administration (not included in this list) should also be administered only as intended, in an intact form.

## SUGAR-FREE PRODUCTS

Listed below, by therapeutic category, is a selection of drug products that contain no sugar. When recommending these products to diabetic patients, keep in mind that many may

contain sorbitol, alcohol, or other sources of carbohydrates. This list should not be considered all-inclusive. Generics and alternate brands of some products may be available. Check product labeling for a current listing of inactive ingredients.

### Analgesics

	Manufacturer
Actamin Maximum Strength Liquid	Cypress

Poly-Vi-Solution Liquid	Mead Johnson
Poly-Vi-Solution w/Iron Liquid	Mead Johnson
Protect Plus Liquid	Gil
Solvite-F Drops	Pharmics
Strovite Forte Syrup	Everett
Supervite Liquid	Seyer Pharmatec
Suplevit Liquid	Gil
Tri-Vi-Sol Drops	Mead Johnson
Tri-Vi-Sol w/Iron Drops	Mead Johnson
Vitafol Syrup	Everett
Vitalize Liquid	Scot-Tussin
Vitamin C/Rose Hips Tablet, Extended Release	ADH Health Products

## DRUGS THAT MAY CAUSE PHOTSENSITIVITY

The drugs in this table are known to cause photosensitivity in some individuals. Effects can range from itching, scaling, rash, and swelling to skin cancer, premature skin aging, skin and eye burns, cataracts, reduced immunity, blood vessel damage, and allergic reactions.

The list is not all-inclusive, and shows only representative brands of each generic. When in doubt, always check specific product labeling. Individuals should be advised to wear protective clothing and to apply sunscreens while taking the medications listed below.

Generic	Brand
Acamprosate	Campral
Acetazolamide	Diamox
Acitretin	Soriatane
Acyclovir	Zovirax
Alendronate	Fosamax
Alitretinoin	Panretin
Almotriptan	Axert
Amiloride/hydrochlorothiazide	Moduretic
Aminolevulinic acid	Levulan Kerastick
Amiodarone	Cordarone, Pacerone
Amitriptyline	Elavil
Amitriptyline/chlordiazepoxide	Limbitro
Amitriptyline/perphenazine	Triavil
Amlodipine/atorvastatin	Caduet
Amoxapine	
Anagrelide	Agrylin
Apripiprazole	Abilify
Atazanavir	Reyataz
Atenolol/chlorthalidone	Tenoretic
Atorvastatin	Lipitor
Atovaquone/proguanil	Malarone
Azatadine/pseudoephedrine	Rynatan, Trinalin
Azithromycin	Zithromax

(Continued on next page)

Generic	Brand
Benazepril	Lotensin
Benazepril/hydrochlorothiazide	Lotensin HCT
Bendroflumethiazide/nadolol	Corzide
Bexarotene	Targretin
Bismuth/metronidazole/tetracycline	Helidac
Bisoprolol/hydrochlorothiazide	Ziac
Brompheniramine/dextromethorphan/phenylephrine	Alacol DM
Brompheniramine/dextromethorphan/pseudoephedrine	Bromfed-DM
Buffered aspirin/pravastatin	Pravigard PAC
Bupropion	Wallbutrin, Zyban
Candesartan/hydrochlorothiazide	Atacand HCT
Capecitabine	Xeloda
Captopril	Capoten
Captopril/hydrochlorothiazide	Capozide
Carbamazepine	Carbatrol, Tegretol, Tegretol-XR
Carbinoxamine/pseudoephedrine	Palgic-D, Palgic-DS, Peditax-D
Carvedilol	Coreg
Celecoxib	Celebrex
Cetirizine	Zyrtec
Cetirizine/pseudoephedrine	Zyrtec-D
Cevimeline	Evoxac
Chlorhexidine gluconate	Hibistat
Chloroquine	Aralen
Chlorothiazide	Diuril
Chlorpheniramine/hydrocodone/pseudoephedrine	Tussend
Chlorpheniramine/phenylephrine/pyrilamine	Rynatan
Chlorpromazine	Thorazine
Chlorpropamide	Diabinese
Chlorthalidone	Thalitone
Chlorthalidone/clonidine	Clorpres
Cidofovir	Vislido
Ciprofloxacin	Cipro
Citalopram	Celexa
Clemastine	Tavist
Clonidine/chlorthalidone	Clorpres
Clozapine	Clozaril, Fazacio
Cromolyn sodium	Gastrocrom
Cyclobenzaprine	Flexeril
Cyproheptadine	Cyproheptadine
Dacarbazine	DTIC-Dome
Dantrolene	Dantrium
Demeclocycline	Declomycin
Desipramine	Norpramin
Diclofenac potassium	Catalfam
Diclofenac sodium	Voltaren
Diclofenac sodium/misoprostol	Arthrotec
Diflunisal	Dolobid
Dihydroergotamine	D.H.E. 45
Diltiazem	Cardizem, Tiazac
Diphenhydramine	Benadryl
Divalproex	Depakote
Doxepin	Sinequan
Doxycycline hyclate	Doryx, Periostat, Vibra-Tabs, Vibramycin

Generic	Brand
Doxycycline monohydrate	Monodox
Duloxetine	Cymbalta
Enalapril	Vasotec
Enalapril/felodipine	Lexxel
Enalapril/hydrochlorothiazide	Vaseretic
Enalaprilat	Vasotec I.V.
Epirubicin	Ellence
Eprosartan mesylate/hydrochlorothiazide	Teveten HCT
Erythromycin/sulfisoxazole	Pediazole
Estazolam	ProSom
Estradiol	Gynodiol, Estrogel
Eszopiclone	Lunesta
Ethionamide	Trecator-SC
Etodolac	Lodine
Felbamate	Felbatol
Fenofibrate	Tricor, Lofibra
Floxuridine	Sterile FUDR
Flucytosine	Ancobon
Fluorouracil	Efudex
Fluoxetine	Prozac, Sarafem
Fluphenazine	Prolixin
Flutamide	Eulexin
Fluvastatin	Lescol
Fluvoxamine	Luvox
Fosinopril	Monopril
Fosphenytoin	Cerebyx
Furosemide	Lasix
Gabapentin	Neurontin
Gatifloxacin	Tequin
Gemfibrozil	Lopid
Gemifloxacin mesylate	Factive
Gentamicin	Garamycin
Glatiramer	Copaxone
Glimepiride	Amaryl
Glipizide	Glucotrol
Glyburide	DiaBeta, Glynase, Micronase
Glyburide/metformin HCl	Glucoavance
Griseofulvin	Fulvicin P/G, Grifulvin, Gris-PEG
Haloperidol	Haldol
Hexachlorophene	pHisoHex
Hydralazine/hydrochlorothiazide	Hydra-zide
Hydrochlorothiazide	HydroDIURIL, Microzide, Oretic
Hydrochlorothiazide/fosinopril	Monopril HCT
Hydrochlorothiazide/lrbesartan	Avalide
Hydrochlorothiazide/lisinopril	Prinzide, Zestoretic
Hydrochlorothiazide/losartan potassium	Hyzaar
Hydrochlorothiazide/methyldopa	Aldoril
Hydrochlorothiazide/moexipril	Uniretic
Hydrochlorothiazide/propranolol	Inderide
Hydrochlorothiazide/quinapril	Accuretic
Hydrochlorothiazide/spironolactone	Aldactazide
Hydrochlorothiazide/telmisartan	Micardis HCT
Hydrochlorothiazide/timolol	Timolide

(Continued on next page)

Generic	Brand
Hydrochlorothiazide/triamterene	Dyazide, Maxzide
Hydrochlorothiazide/valsartan	Diovan HCT
Hydroflumethiazide	Hydroflumethiazide
Hydroxychloroquine	Plaquenil
Hypericum	Kira, St. John's wort
Hypericum/vitamin B <sub>1</sub> /vitamin C/kava-kava	One-A-Day Tension & Mood
Ibuprofen	Motrin
Imatinib Mesylate	Gleevec
Imipramine	Tofranil
Imiquimod	Aldara
Indapamide	Lozol
Interferon alfa-2b, recombinant	Intron A
Interferon alfa-n3 (human leukocyte derived)	Alferon-N
Interferon beta-1a	Avonex
Interferon beta-1b	Betaseron
Irbesartan/hydrochlorothiazide	Avalide
Isoniazid/pyrazinamide/rifampin	Rifater
Isotretinoin	Accutane, Amnesteem
Itraconazole	Sporanox
Ketoprofen	Orudis, Oruvail
Lamotrigine	Lamictal
Leuprolide	Lupron
Levamisole	Levamisole
Lisinopril	Prinivil, Zestril
Lisinopril/hydrochlorothiazide	Prinivil, Zestoretic
Lomefloxacin	Maxaquin
Loratadine	Claritin
Loratadine/pseudoephedrine	Claritin-D
Losartan	Cozaar
Losartan/hydrochlorothiazide	Hyzaar
Lovastatin	Altoprev, Mevacor
Lovastatin/niacin	Advicor
Maprotiline	Maprotiline
Mefenamic acid	Ponstel
Meloxicam	Mobic
Mesalamine	Pentasa
Methazolamide	
Methotrexate	Trexall
Methoxsalen	Uvadex, Oxsoralen, 8-MOP
Methyclothiazide	Enduron
Methyldopa/hydrochlorothiazide	Aldoril
Metolazone	Mykrox, Zaroxolyn
Minocycline	Dynacin, Minocin
Mirtazapine	Remeron
Moexipril	Univasc
Moexipril/hydrochlorothiazide	Uniretic
Moxifloxacin	Avelox
Nabumetone	Relafen
Nadolol/bendroflumethiazide	Corzide
Nalidixic acid	Nalidixic acid
Naproxen	Naprosyn, EC-Naprosyn
Naproxen sodium	Anaprox, Naprelan
Naratriptan	Amerge

Generic	Brand
Nefazodone	Serzone
Nifedipine	Adalat CC, Procardia
Nisoldipine	Sular
Norfloracin	Noroxin
Nortriptyline	Pamelor
Ofloxacin	Floxin
Olanzapine	Zyprexa
Olanzapine/fluoxetine	Symbyax
Olmesartan medoxomil/hydrochlorothiazide	Benicar HCT
Olsalazine	Dipentum
Oxaprozin	Daypro
Oxcarbazepine	Trileptal
Oxycodone	Roxicodone
Oxytetracycline	Terramycin
Pantoprazole	Protonix
Paroxetine	Paxil
Pastinaca sativa	Parsnip
Pentosan polysulfate	Elmiron
Pentostatin	Nipent
Perphenazine	Perphenazine
Pilocarpine	Salagen
Piroxicam	Feldene
Polythiazide	Renese
Polythiazide/prazosin	Minizide
Porfimer sodium	Photofrin
Pravastatin	Pravachol
Prochlorperazine	Compazine, Compro
Promethazine	Phenergan
Protriptyline	Vivactil
Pyrazinamide	Pyrazinamide
Quetiapine	Seroquel
Quinapril	Accupril
Quinapril/hydrochlorothiazide	Accuretic
Quinidine gluconate	Quinidine
Quinidine sulfate	Quinidex
Rabeprazole sodium	Aciphex
Ramipril	Altace
Riluzole	Rilutek
Risperidone	Risperdal, Risperdal Consta
Ritonavir	Norvir
Rizatriptan	Maxalt
Ropinirole	Requip
Rosuvastatin	Crestor
Ruta graveolens	Rue
Saquinavir	Fortovase
Saquinavir mesylate	Invirase
Selegiline	Eldepryl
Sertraline	Zoloft
Sibutramine	Meridia
Sildenafil	Viagra
Simvastatin	Zocor
Simvastatin/ezetimibe	Vytorin
Somatropin	Serostim

(Continued on next page)

Generic	Brand
Sotalol	Betapace, Betapace
Sulfamethoxazole/trimethoprim	Bactrim, Septra
Sulfasalazine	Azulfidine
Sulindac	Clinoril
Sumatriptan	Imitrex
Tacrolimus	Prograf, Protopic
Tazarotene	Tazorac
Telmisartan/hydrochlorothiazide	Micardis HCT
Tetracycline	Sumycin
Thalidomide	Thalomid
Thioridazine hydrochloride	Mellaril
Thiothixene	Navane
Tiagabine	Gabitril
Tolazamide	Tolazamide
Tolbutamide	Tolbutamide
Topiramate	Topamax
Tretinoin	Retin-A
Triamcinolone	Azmacort
Triamterene	Dyrenium
Triamterene/hydrochlorothiazide	Dyazide, Maxzide
Trifluoperazine	Trifluoperazine
Trimipramine	Surmontil
Trovafloxacin	Trovan
Valacyclovir	Valtrex
Valdecoxib	Bextra
Valproate	Depacon
Valproic acid	Depakene
Valsartan/hydrochlorothiazide	Diovan HCT
Vardenafil	Levitra
Venlafaxine	Effexor
Verteporfin	Visudyne
Vinblastine	Vinblastine
Voriconazole	Vfend
Zalcitabine	Hivid
Zaleplon	Sonata
Ziprasidone	Geodon
Zolmitriptan	Zomig
Zolpidem	Ambien

## DRUG/ALCOHOL INTERACTIONS

Product	Interaction	Onset	Severity
ACETAMINOPHEN	ETHANOL Concurrent use of ACETAMINOPHEN and ETHANOL may result in an increased risk of hepatotoxicity.	2	2
ACETOPHENAZINE	ETHANOL Concurrent use of ACETOPHENAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.	1	2
ACITRETIN	ETHANOL Concurrent use of ACITRETIN and ETHANOL may result in a prolonged risk of teratogenicity.	2	1
ALFENTANIL	ETHANOL Concurrent use of ALFENTANIL and ETHANOL may result in decreased therapeutic effects for alfentanil.	2	2
ALPRAZOLAM	ETHANOL Concurrent use of ALPRAZOLAM and ETHANOL may result in increased sedation.	1	2
AMITRIPTYLINE	ETHANOL Concurrent use of AMITRIPTYLINE and ETHANOL may result in enhanced CNS depression and impairment of motor skills.	1	2
AMOBARBITAL	ETHANOL Concurrent use of AMOBARBITAL and ETHANOL may result in excessive CNS depression.	1	2
AMOXAPINE	ETHANOL Concurrent use of AMOXAPINE and ETHANOL may result in enhanced drowsiness and impairment of motor skills.	1	2
AMPRENAVIR	ETHANOL Concurrent use of AMPRENAVIR and ETHANOL may result in an increased risk of propylene glycol toxicity (seizures, tachycardia, lactic acidosis, renal toxicity, and hemolysis).	2	1
APROBARBITAL	ETHANOL Concurrent use of APROBARBITAL and ETHANOL may result in excessive CNS depression.	1	2
ASPIRIN	ETHANOL Concurrent use of ASPIRIN and ETHANOL may result in increased gastrointestinal blood loss.	1	2
BUPROPION	ETHANOL Concurrent use of BUPROPION and ETHANOL may result in an increased risk of seizures.	2	1
BUTABARBITAL	ETHANOL Concurrent use of BUTABARBITAL and ETHANOL may result in excessive CNS depression.	1	2
BUTALBITAL	ETHANOL Concurrent use of BUTALBITAL and ETHANOL may result in excessive CNS depression.	1	2
CALAMUS	ETHANOL Concurrent use of CALAMUS and ETHANOL may result in increased sedation.	1	2
CANNABIS	ETHANOL Concurrent use of CANNABIS and ETHANOL may result in increased intoxication.	1	2
CARVEDILOL, PHOSPHATE	ETHANOL Concurrent use of CARVEDILOL, PHOSPHATE and ETHANOL may result in faster than normal rate of release of carvedilol phosphate.	1	2

(Continued on next page)

Product	Interaction	Onset	Severity
CEFAMANDOLE	ETHANOL Concurrent use of CEFAMANDOLE and ETHANOL may result in disulfiram-like reactions.	2	1
CEFMENOXINE	ETHANOL Concurrent use of CEFMENOXINE and ETHANOL may result in disulfiram-like reactions.	1	1
CEFOPERAZONE	ETHANOL Concurrent use of CEFOPERAZONE and ETHANOL may result in disulfiram-like reactions.	2	1
CEFOTETAN	ETHANOL Concurrent use of CEFOTETAN and ETHANOL may result in disulfiram-like reactions.	2	1
CHAPARRAL	ETHANOL Concurrent use of CHAPARRAL and ETHANOL may result in elevated liver transaminases with or without concomitant hepatic damage.	1	2
CHLORAL HYDRATE	ETHANOL Concurrent use of CHLORAL HYDRATE and ETHANOL may result in increased sedation.	1	3
CHLORDIAZEPOXIDE	ETHANOL Concurrent use of CHLORDIAZEPOXIDE and ETHANOL may result in increased sedation.	1	2
CHLORPROMAZINE	ETHANOL Concurrent use of CHLORPROMAZINE and ETHANOL may result in increased sedation.	1	2
CHLORPROPAMIDE	ETHANOL Concurrent use of CHLORPROPAMIDE and ETHANOL may result in disulfiram-like reactions.	1	1
CIMETIDINE	ETHANOL Concurrent use of CIMETIDINE and ETHANOL may result in increased ethanol concentrations.	1	3
CISAPRIDE	ETHANOL Concurrent use of CISAPRIDE and ETHANOL may result in increased blood levels of ethanol.	1	2
CITALOPRAM	ETHANOL Concurrent use of CITALOPRAM and ETHANOL may result in potentiation of the cognitive and motor effects of alcohol.	0	2
CLOMIPRAMINE	ETHANOL Concurrent use of CLOMIPRAMINE and ETHANOL may result in enhanced drowsiness and impairment of motor skills.	1	2
CLORAZEPATE	ETHANOL Concurrent use of CLORAZEPATE and ETHANOL may result in increased sedation.	1	2
COCAINE	ETHANOL Concurrent use of COCAINE and ETHANOL may result in increased heart rate and blood pressure.	1	2
CODEINE	ETHANOL Concurrent use of CODEINE and ETHANOL may result in increased sedation.	1	2
COMFREY	ETHANOL Concurrent use of COMFREY and ETHANOL may result in elevated inner transaminases with or without concomitant hepatic damage.	1	1
CYCLOSERINE	ETHANOL Concurrent use of CYCLOSERINE and ETHANOL may result in an increased risk of seizures.	1	1

Product	Interaction	Onset	Severity
DESIPRAMINE	ETHANOL Concurrent use of DESIPRAMINE and ETHANOL may result in enhanced drowsiness and impairment of motor skills.	1	2
DIAZEPAM	ETHANOL Concurrent use of DIAZEPAM and ETHANOL may result in increased sedation.	1	2
DIMETHINDENE	ETHANOL Concurrent use of DIMETHINDENE and ETHANOL may result in increased sedation.	1	2
DIPHENHYDRAMINE	ETHANOL Concurrent use of DIPHENHYDRAMINE and ETHANOL may result in increased sedation.	1	2
DISULFIRAM	ETHANOL Concurrent use of DISULFIRAM and ETHANOL may result in ethanol intolerance.	1	1
DOTHIEPIN	ETHANOL Concurrent use of ETHANOL and DOTHIEPIN may result in enhanced drowsiness and impairment of motor skills.	1	2
DOXEPIN	ETHANOL Concurrent use of DOXEPIN and ETHANOL may result in enhanced drowsiness and impairment of motor skills.	1	2
ESCITALOPRAM	ETHANOL Concurrent use of ESCITALOPRAM and ETHANOL may result in potentiation of the cognitive and motor effects of alcohol.	0	2
ESZOPICLONE	ETHANOL Concurrent use of ESZOPICLONE and ETHANOL may result in impaired psychomotor functions and risk of increased sedation.	1	2
ETEROBARB	ETHANOL Concurrent use of ETEROBARB and ETHANOL may result in excessive CNS depression.	1	2
ETHOPROPAZINE	ETHANOL Concurrent use of ETHOPROPAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.	1	2
FLUNITRAZEPAM	ETHANOL Concurrent use of FLUNITRAZEPAM and ETHANOL may result in excessive sedation and psychomotor impairment.	1	2
FLUPHENAZINE	ETHANOL Concurrent use of FLUPHENAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.	1	2
FOMEPIZOLE	ETHANOL Concurrent use of FOMEPIZOLE and ETHANOL may result in the reduced elimination of both drugs.	2	2
FOSPHENYTOIN	ETHANOL Concurrent use of FOSPHENYTOIN and ETHANOL may result in decreased phenytoin serum concentrations, increased seizure potential, and additive CNS depressant effects.	1	2
FURAZOLIDONE	ETHANOL Concurrent use of FURAZOLIDONE and ETHANOL may result in disulfiram-like reactions.	1	1
GERMANDER	ETHANOL Concurrent use of GERMANDER and ETHANOL may result in elevated liver transaminases with or without concomitant hepatic damage.	2	1
GLIPIZIDE	ETHANOL Concurrent use of GLIPIZIDE and ETHANOL may result in prolonged hypoglycemia and disulfiram-like reactions.	1	1

(Continued on next page)

Product	Interaction	Onset	Severity
GLICLAZIDE	ETHANOL Concurrent use of ETHANOL and GLICLAZIDE may result in prolonged hypoglycemia and disulfiram-like reactions.	1	1
GLUTETHIMIDE	ETHANOL Concurrent use of GLUTETHIMIDE and ETHANOL may result in increased sedation.	1	2
GLYBURIDE	ETHANOL Concurrent use of GLYBURIDE and ETHANOL may result in prolonged hypoglycemia and disulfiram-like reactions.	1	2
GOSSYPOL	ETHANOL Concurrent use of GOSSYPOL and ETHANOL may result in delayed effects of gossypol and/or increased toxic effects of ethanol.	1	2
GRISEOFULVIN	ETHANOL Concurrent use of GRISEOFULVIN and ETHANOL may result in disulfiram-like reactions.	1	1
GUAR GUM	ETHANOL Concurrent use of GUAR GUM and ETHANOL may result in increased intoxication effects of ethanol.	2	2
GUARANA	ETHANOL Concurrent use of GUARANA and ETHANOL may result in increased risk of ethanol intoxication.	1	3
HYDROCODONE	ETHANOL Concurrent use of HYDROCODONE and ETHANOL may result in increased sedation.	1	2
HYDROMORPHONE	ETHANOL Concurrent use of HYDROMORPHONE and ETHANOL may result in increased sedation.	1	2
IMIPRAMINE	ETHANOL Concurrent use of IMIPRAMINE and ETHANOL may result in enhanced drowsiness and impairment of motor skills.	1	2
INSULIN	ETHANOL Concurrent use of INSULIN and ETHANOL may result in increased hypoglycemia.	1	2
INSULIN LISPRO, HUMAN	ETHANOL Concurrent use of INSULIN LISPRO, HUMAN and ETHANOL and may result in increased hypoglycemia.	1	2
ISONIAZID	ETHANOL Concurrent use of ISONIAZID and ETHANOL may result in decreased isoniazid concentrations and disulfiram-like reactions.	2	1
ISOTRETINOIN	ETHANOL Concurrent use of ISOTRETINOIN and ETHANOL may result in disulfiram-like reactions.	1	1
KAVA	ETHANOL Concurrent use of KAVA and ETHANOL may result in increased CNS depression and/or increased risk of hepatotoxicity.	1	2
KETOCONAZOLE	ETHANOL Concurrent use of KETOCONAZOLE and ETHANOL may result in disulfiram-like reactions (flushing, vomiting, increased respiratory rate, tachycardia).	1	1
LOFEPRAMINE	ETHANOL Concurrent use of LOFEPRAMINE and ETHANOL may result in enhanced drowsiness and impairment of motor skills.	1	2
LORAZEPAM	ETHANOL Concurrent use of LORAZEPAM and ETHANOL may result in increased sedation.	1	2

Product	Interaction	Onset	Severity
MA HUANG	ETHANOL Concurrent use of MA HUANG and ETHANOL may result in effects on mental status.	1	1
MATE	ETHANOL Concurrent use of MATE and ETHANOL may result in increased risk of ethanol intoxication.	1	3
MEPERIDINE	ETHANOL Concurrent use of MEPERIDINE and ETHANOL may result in increased sedation.	1	2
MEPHOBARBITAL	ETHANOL Concurrent use of MEPHOBARBITAL and ETHANOL may result in excessive CNS depression.	1	2
MEPROBAMATE	ETHANOL Concurrent use of MEPROBAMATE and ETHANOL may result in increased sedation.	1	2
MESORIDAZINE	ETHANOL Concurrent use of MESORIDAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.	1	2
METFORMIN	ETHANOL Concurrent use of METFORMIN and ETHANOL may result in an increased risk of lactic acidosis.	2	2
METHADONE	ETHANOL Concurrent use of METHADONE and ETHANOL may result in increased sedation.	1	2
METHOHEXITAL	ETHANOL Concurrent use of METHOHEXITAL and ETHANOL may result in excessive CNS depression.	1	2
METHOTREXATE	ETHANOL Concurrent use of METHOTREXATE and ETHANOL may result in increased hepatotoxicity.	2	2
METHOTRIMEPRAZINE	ETHANOL Concurrent use of METHOTRIMEPRAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.	1	2
METRONIDAZOLE	ETHANOL Concurrent use of METRONIDAZOLE and ETHANOL may result in disulfiram-like reactions (flushing, increased respiratory rate, tachycardia) or sudden death.	1	1
MIRTAZAPINE	ETHANOL Concurrent use of MIRTAZAPINE and ETHANOL may result in psychomotor impairment.	1	2
MORPHINE	ETHANOL Concurrent use of MORPHINE and ETHANOL may result in increased risk of respiratory depression, hypotension, profound sedation, or coma.	1	2
MORPHINE SULFATE LIPOSOME	ETHANOL Concurrent use of MORPHINE SULFATE LIPOSOME and ETHANOL may result in increased risk of respiratory depression, hypotension, profound sedation, or coma.	1	1
MOXALACTAM	ETHANOL Concurrent use of ETHANOL and MOXALACTAM may result in disulfiram-like reactions.	2	1
NEFAZODONE	ETHANOL Concurrent use of NEFAZODONE and ETHANOL may result in an increased risk of CNS side effects.	1	3

(Continued on next page)

Product	Interaction	Onset	Severity
NIACIN	ETHANOL Concurrent use of NIACIN and ETHANOL may result in increased side effects of flushing and pruritus.	0	2
NILUTAMIDE	ETHANOL Concurrent use of NILUTAMIDE and ETHANOL may result in an increased risk of ethanol intolerance (facial flushing, malaise, and hypotension).	1	3
NITROGLYCERIN	ETHANOL Concurrent use of NITROGLYCERIN and ETHANOL may result in hypotension.	1	2
NORTRIPTYLINE	ETHANOL Concurrent use of NORTRIPTYLINE and ETHANOL may result in enhanced drowsiness and impairment of motor skills.	1	2
OLANZAPINE	ETHANOL Concurrent use of OLANZAPINE and ETHANOL may result in excessive CNS depression.	1	2
OXYCODONE	ETHANOL Concurrent use of OXYCODONE and ETHANOL may result in increased sedation.	1	2
OXYMORPHONE	ETHANOL Concurrent use of OXYMORPHONE and ETHANOL may result in increased oxymorphone plasma levels (extended-release formulation) and additive CNS/ respiratory depression.	0	1
PARALDEHYDE	ETHANOL Concurrent use of PARALDEHYDE and ETHANOL may result in metabolic acidosis.	2	2
PAROXETINE	ETHANOL Concurrent use of PAROXETINE and ETHANOL may increase the risk of mental and motor-skill impairment.	1	3
PENNYROYAL	ETHANOL Concurrent use of PENNYROYAL and ETHANOL may result in elevated liver transaminases with or without concomitant hepatic damage.	1	1
PENTAZOCINE	ETHANOL Concurrent use of PENTAZOCINE and ETHANOL may result in increased sedation.	1	2
PERPHENAZINE	ETHANOL Concurrent use of PERPHENAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.	1	2
PHENELZINE	ETHANOL Concurrent use of PHENELZINE and ETHANOL may result in hypertension urgency or emergency.	1	2
PHENOBARBITAL	ETHANOL Concurrent use of PHENOBARBITAL and ETHANOL may result in excessive CNS depression.	1	2
PHENYTOIN	ETHANOL Concurrent use of PHENYTOIN and ETHANOL may result in decreased phenytoin serum concentrations, increased seizure potential, and additive CNS depressant effects.	1	2
PIPOTIAZINE	ETHANOL Concurrent use of PIPOTIAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.	1	2
PRIMIDONE	ETHANOL Concurrent use of PRIMIDONE and ETHANOL may result in excessive CNS depression.	1	2

Product	Interaction	Onset	Severity
PROCARBAZINE	ETHANOL Concurrent use of PROCARBAZINE and ETHANOL may result in disulfiram-like reactions and increased sedation.	1	1
PROCHLORPERAZINE	ETHANOL Concurrent use of PROCHLORPERAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.	1	2
PROMAZINE	ETHANOL Concurrent use of PROMAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.	1	2
PROPIOMAZINE	ETHANOL Concurrent use of PROPIOMAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.	1	2
PROTRIPTYLINE	ETHANOL Concurrent use of PROTRIPTYLINE and ETHANOL may result in enhanced drowsiness and impairment of motor skills.	1	2
QUETIAPINE	ETHANOL Concurrent use of QUETIAPINE and ETHANOL may result in potentiation of the cognitive and motor effects of alcohol.	1	2
SECOBARBITAL	ETHANOL Concurrent use of SECOBARBITAL and ETHANOL may result in excessive CNS depression.	1	2
SERTRALINE	ETHANOL Concurrent use of SERTRALINE and ETHANOL may increase the risk of mental and motor-skill impairment.	1	2
SULFAMETHOXAZOLE	ETHANOL Concurrent use of SULFAMETHOXAZOLE and ETHANOL may result in disulfiram-like reactions (flushing, sweating, palpitations, drowsiness).	1	1
TACROLIMUS	ETHANOL Concurrent use of TACROLIMUS and ETHANOL may result in alcohol-related flushing and rash.	1	3
TADALAFIL	ETHANOL Concurrent use of TADALAFIL and ETHANOL may result in an increased risk of hypotension and orthostatic signs and symptoms.	1	2
TEMAZEPAM	ETHANOL Concurrent use of TEMAZEPAM and ETHANOL may result in impaired psychomotor functions.	1	2
THIETHYLPERAZINE	ETHANOL Concurrent use of THIETHYLPERAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.	1	2
THIEOPENTAL	ETHANOL Concurrent use of THIEOPENTAL and ETHANOL may result in excessive CNS depression.	1	2
THIORIDAZINE	ETHANOL Concurrent use of THIORIDAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.	1	2
TIZANIDINE	ETHANOL Concurrent use of TIZANIDINE and ETHANOL may increase the risk of tizanidine adverse effects (excessive CNS depression).	1	2
TOLAZAMIDE	ETHANOL Concurrent use of TOLAZAMIDE and ETHANOL may result in prolonged hypoglycemia and disulfiram-like reactions.	1	1

(Continued on next page)

Product	Interaction	Onset	Severity
TOLAZOLINE	ETHANOL Concurrent use of TOLAZOLINE and ETHANOL may result in disulfiram-like reactions.	2	1
TOLBUTAMIDE	ETHANOL Concurrent use of TOLBUTAMIDE and ETHANOL may result in prolonged hypoglycemia and disulfiram-like reactions.	1	1
TRAMADOL	ETHANOL Concurrent use of TRAMADOL and ETHANOL may increase the risk of excessive CNS depression.	1	2
TRANLYCYPROMINE	ETHANOL Concurrent use of TRANLYCYPROMINE and ETHANOL may result in hypertensive urgency or emergency.	1	2
TRIAZOLAM	ETHANOL Concurrent use of TRIAZOLAM and ETHANOL may result in increased sedation.	1	2
TRIFLUPERAZINE	ETHANOL Concurrent use of TRIFLUPERAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.	1	2
TRIFLUPROMAZINE	ETHANOL Concurrent use of TRIFLUPROMAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.	1	2
TRIMETHOPRIM	ETHANOL Concurrent use of ETHANOL and COTRIMOXAZOLE may result in disulfiram-like reactions.	1	1
TRIMIPRAMINE	ETHANOL Concurrent use of TRIMIPRAMINE and ETHANOL may result in enhanced drowsiness and impairment of motor skills.	1	2
VALERIAN	ETHANOL Concurrent use of VALERIAN and ETHANOL may result in increased sedation.	1	2
VENLAFAXINE	ETHANOL Concurrent use of VENLAFAXINE and ETHANOL may result in an increased risk of CNS effects.	1	3
VERAPAMIL	ETHANOL Concurrent use of VERAPAMIL and ETHANOL may result in enhanced ethanol intoxication (impaired psychomotor functioning).	1	2
WARFARIN	ETHANOL Concurrent use of WARFARIN and ETHANOL may result in increased or decreased international normalized ratio (INR) or prothrombin time.	2	2
YOHIMBINE	ETHANOL Concurrent use of YOHIMBINE and ETHANOL may result in increased ethanol intoxication and increased anxiety and blood pressure.	1	2
ZALEPLON	ETHANOL Concurrent use of ZALEPLON and ETHANOL may result in impaired psychomotor functions.	1	2
ZOLPIDEM	ETHANOL Concurrent use of ZOLPIDEM and ETHANOL may result in increased sedation.	1	2

ONSET: 0 = Unspecified

1 = Rapid (within 24 hours)

2 = Delayed (after 24 hours)

SEVERITY: 1 = Major (possibly life threatening or potential permanent damage)

2 = Moderate (may exacerbate patient's condition)

3 = Minor (little if any clinical effect)

Note: Disulfiram-like reactions include nausea, vomiting, diarrhea, flushing, tachycardia, and hypotension. Reprinted with permission from *The Drug Topics Red Book*. Montvale, NJ: Thomson Medical Economics, 2007.

**DRUG/TOBACCO INTERACTIONS**

Product	Interaction	Onset	Severity
ALPRAZOLAM	TOBACCO Concurrent use of ALPRAZOLAM and TOBACCO may result in decreased alprazolam plasma concentrations and efficacy.	0	2
CONTRACEPTIVES, COMBINATION	TOBACCO Concurrent use of CONTRACEPTIVES, COMBINATION and TOBACCO may result in an increased risk of cardiovascular disease.	2	3
ERLOTINIB	TOBACCO Concurrent use of ERLOTINIB and TOBACCO may result in increased erlotinib clearance and reduced serum concentrations.	0	2
FLUVOXAMINE	TOBACCO Concurrent use of FLUVOXAMINE and TOBACCO may result in increased fluvoxamine metabolism.	2	3
IMIPRAMINE	TOBACCO Concurrent use of IMIPRAMINE and TOBACCO may result in decreased imipramine concentrations.	2	2
PENTAZOCINE	TOBACCO Concurrent use of PENTAZOCINE and TOBACCO may result in decreased pentazocine concentrations.	2	2
PROPOXYPHENE	TOBACCO Concurrent use of PROPOXYPHENE and TOBACCO may result in decreased propoxyphene concentrations.	2	2
ROPINIROLE	TOBACCO Concurrent use of ROPINIROLE and TOBACCO may result in decreased ropinirole plasma concentrations and efficacy.	0	2
THEOPHYLLINE	TOBACCO Concurrent use of THEOPHYLLINE and TOBACCO may result in decreased theophylline concentrations.	2	2
TOLBUTAMIDE	TOBACCO Concurrent use of TOLBUTAMIDE and TOBACCO may result in decreased tolbutamide concentrations.	2	2
WARFARIN	TOBACCO Concurrent use of WARFARIN and TOBACCO may result in increased or decreased international normalized ratio (INR) or prothrombin time.	2	2

ONSET: 0 = Unspecified

1 = Rapid (within 24 hours)

2 = Delayed (after 24 hours)

SEVERITY: 1 = Major (possibly life threatening or potential permanent damage)

## USE-IN-PREGNANCY RATINGS

The U.S. Food and Drug Administration's Use-in-Pregnancy rating system weighs the degree to which available information

has ruled out risk to the fetus against the drug's potential benefit to the patient. Below is a listing of drugs (by generic name) for which ratings are available.

### X

#### CONTRAINDICATED IN PREGNANCY

*Studies in animals or humans, or investigational or post-marketing reports, have demonstrated fatal risk which clearly outweighs any possible benefit to the patient.*

Acetohydroxamic Acid  
 Acitretin  
 Amlodipine Besylate/Atorvastatin Calcium  
 Amprenavir  
 Anisindione  
 Atorvastatin Calcium  
 Bexarotene  
 Bicalutamide  
 Bosentan  
 Cetorelix Acetate  
 Choriogonadotropin Alfa  
 Chorionic Gonadotropin  
 Clomiphene Citrate  
 Desogestrel/Ethinyl Estradiol  
 Diclofenac Sodium/Misoprostol  
 Dihydroergotamine Mesylate  
 Dutasteride  
 Estazolam  
 Estradiol  
 Estradiol Acetate  
 Estradiol Cypionate/  
 Medroxyprogesterone Acetate  
 Estradiol Valerate  
 Estradiol/Levonorgestrel  
 Estradiol/Norethindrone Acetate  
 Estrogens, Conjugated  
 Estrogens, Conjugated, Synthetic A  
 Estrogens, Conjugated/  
 Medroxyprogesterone Acetate  
 Estrogens, Esterified  
 Estrogens, Esterified/  
 Methyltestosterone  
 Estropipate  
 Ethinyl Estradiol/Drospirenone  
 Ethinyl Estradiol/Ethinodiol  
 Diacetate

Ethinyl Estradiol/Etonogestrel  
 Ethinyl Estradiol/Ferrous Fumarate/  
 Norethindrone Acetate  
 Ethinyl Estradiol/Levonorgestrel  
 Ethinyl Estradiol/Norelgestromin  
 Ethinyl Estradiol/Norethindrone  
 Ethinyl Estradiol/Norethindrone  
 Acetate  
 Ethinyl Estradiol/Norgestimate  
 Ethinyl Estradiol/Norgestrel  
 Ezelimibe/Simvastatin  
 Finasteride  
 Fluorouracil  
 Fluoxymesterone  
 Flurazepam Hydrochloride  
 Fluvastatin Sodium  
 Follitropin Alfa  
 Follitropin Beta  
 Ganirelix Acetate  
 Goserelin Acetate  
 Histrelin Acetate  
 Hydromorphone Hydrochloride  
 Interferon Alfa-2B, Recombinant/  
 Ribavirin  
 Iodine 1 131 Tositumomab/  
 Tositumomab  
 Isotretinoin  
 Leflunomide  
 Leuprolide Acetate  
 Levonorgestrel  
 Lovastatin  
 Lovastatin/Niacin  
 Medroxyprogesterone Acetate  
 Megestrol Acetate  
 Menotropins  
 Mequinol/Tretinoin  
 Mestranol/Norethindrone  
 Methotrexate Sodium  
 Methyltestosterone  
 Miglustat  
 Misoprostol  
 Nafarelin Acetate  
 Norethindrone  
 Norethindrone Acetate  
 Norgestrel  
 Oxandrolone  
 Oxymetholone

Pilcamycin  
 Pravastatin Sodium  
 Pravastatin Sodium/Aspirin Buffered  
 Raloxifene Hydrochloride  
 Ribavirin  
 Rosuvastatin Calcium  
 Simvastatin  
 Tazarotene  
 Testosterone  
 Testosterone Enanthate  
 Thalidomide  
 Tositumomab  
 Triptorelin Pamoate  
 Urofollitropin  
 Warfarin Sodium

### D

#### POSITIVE EVIDENCE OF RISK

*Investigational or postmarketing data show risk to the fetus. Nevertheless, potential benefits may outweigh the potential risk.*

Alitretinoin  
 Alprazolam  
 Altretamine  
 Amiodarone Hydrochloride  
 Amiodipine Besylate/Benazepril  
 Hydrochloride  
 Anastrozole  
 Arsenic Trioxide  
 Aspirin Buffered/Pravastatin Sodium  
 Aspirin/Dipyridamole  
 Atenolol  
 Azathioprine  
 Azathioprine Sodium  
 Benazepril Hydrochloride\*  
 Benazepril Hydrochloride/  
 Hydrochlorothiazide\*  
 Bortezomib  
 Busulfan  
 Candesartan Cilexetil\*  
 Candesartan Cilexetil/  
 Hydrochlorothiazide\*

\*Category C or D depending on the trimester the drug is given.

Capecitabine  
 Captopril\*  
 Carbamazepine  
 Carboplatin  
 Carmustine (Bcnu)  
 Chlorambucil  
 Cladribine  
 Clofarabine  
 Clonazepam  
 Cytarabine Liposome  
 Dactinomycin  
 Daunorubicin Citrate Liposome  
 Daunorubicin Hydrochloride  
 Demeclocycline Hydrochloride  
 Diazepam  
 Divalproex Sodium  
 Docetaxel  
 Doxorubicin Hydrochloride  
 Doxorubicin Hydrochloride  
 Liposome  
 Doxycycline Calcium  
 Doxycycline Hyclate  
 Doxycycline Monohydrate  
 Efavirenz  
 Enalapril Maleate\*  
 Enalapril Maleate/  
 Hydrochlorothiazide\*  
 Epirubicin Hydrochloride  
 Eprosartan Mesylate  
 Eriotinib  
 Exemestane  
 Felodipine/Enalapril Maleate  
 Floxuridine  
 Fludarabine Phosphate  
 Flutamide  
 Fosinopril Sodium\*  
 Fosinopril Sodium/  
 Hydrochlorothiazide\*  
 Fosphenytoin Sodium  
 Fulvestrant  
 Gefitinib  
 Gemcitabine Hydrochloride  
 Gemtuzumab Ozogamicin  
 Goserelin Acetate  
 Ibritumomab Tiuxetan  
 Idarubicin Hydrochloride  
 Ifosfamide  
 Imatinib Mesylate  
 Irbesartan\*  
 Irbesartan/Hydrochlorothiazide\*  
 Irinotecan Hydrochloride  
 Letrozole

Lisinopril\*  
 Lisinopril/Hydrochlorothiazide\*  
 Lithium Carbonate  
 Losartan Potassium\*  
 Losartan Potassium/  
 Hydrochlorothiazide\*  
 Mechlorethamine Hydrochloride  
 Melphalan  
 Melphalan Hydrochloride  
 Mephobarbital  
 Mercaptopurine  
 Methimazole  
 Midazolam Hydrochloride  
 Minocycline Hydrochloride  
 Mitoxantrone Hydrochloride  
 Moexipril Hydrochloride\*  
 Moexipril Hydrochloride/  
 Hydrochlorothiazide\*  
 Nelarabine  
 Neomycin Sulfate/Polymyxin  
 B Sulfate  
 Nicotine  
 Olmesartan Medoxomil  
 Oxaliplatin  
 Pamidronate Disodium  
 Pemetrexed  
 Penicillamine  
 Pentobarbital Sodium  
 Pentostatin  
 Perindopril Erbumine\*  
 Phenytoin  
 Procarbazine Hydrochloride  
 Quinapril Hydrochloride\*  
 Quinapril Hydrochloride/  
 Hydrochlorothiazide\*  
 Ramipril\*  
 Sorafenib  
 Streptomycin Sulfate  
 Sunitinib  
 Tamoxifen Citrate  
 Telmisartan  
 Telmisartan/Hydrochlorothiazide  
 Temozolomide  
 Thioguanine  
 Tigecycline  
 Tobramycin  
 Topotecan Hydrochloride  
 Toremifene Citrate  
 Trandolapril\*  
 Trandolapril/Verapamil  
 Hydrochloride\*  
 Tretinoin

Valproate Sodium  
 Valproic Acid  
 Valsartan\*  
 Valsartan/Hydrochlorothiazide\*  
 Vinorelbine Tartrate  
 Voriconazole  
 Zoledronic Acid

## C

### RISK CANNOT BE RULED OUT

*Human studies are lacking, and animal studies are either positive for risk or are lacking as well. However, potential benefits may outweigh the potential risk.*

Abacavir Sulfate  
 Abacavir Sulfate/Lamivudine  
 Abacavir Sulfate/Lamivudine/  
 Zidovudine  
 Abciximab  
 Acamprosate Calcium  
 Acetaminophen  
 Acetaminophen/Butalbital/Caffeine  
 Acetaminophen/Caffeine/  
 Chlorpheniramine Maleate/  
 Hydrocodone Bitartrate/  
 Phenylephrine Hydrochloride  
 Acetazolamide  
 Acetazolamide Sodium  
 Acyclovir  
 Adapalene  
 Adefovir Dipivoxil  
 Adenosine  
 Alatroflaxacin Mesylate  
 Albendazole  
 Albumin (Human)  
 Albuterol  
 Albuterol Sulfate  
 Albuterol Sulfate/Ipratropium  
 Bromide  
 Alclometasone Dipropionate  
 Aldesleukin  
 Alemtuzumab  
 Alendronate Sodium  
 Alendronate Sodium/Cholecalciferol  
 Altopurinol Sodium  
 Almotriptan Malate  
 Alpha 1-Proteinase Inhibitor (Human)  
 Alprostadil

*(Continued on next page)*

\*Category C or D depending on the trimester the drug is given.

Alteplase	Benzoyl Peroxide	Carbetapentane Tannate/ Chlorpheniramine Tannate/ Ephedrine Tannate/Phenylephrine Tannate
Amantadine Hydrochloride	Benzoyl Peroxide/Clindamycin	Carbidopa/Entacapone/Levodopa
Amifostine	Benzoyl Peroxide/Erythromycin	Carbidopa/Levodopa
Aminocaproic Acid	Betamethasone Dipropionate	Carbinoxamine Maleate/ Dextromethorphan
Aminohippurate Sodium	Betamethasone Dipropionate/ Chlotrimazole	Hydrobromide/Pseudoephedrine Hydrochloride
Aminolevulinic Acid Hydrochloride	Betamethasone Valerate	Carteolol Hydrochloride
Aminosalicylic Acid	Betaxolol Hydrochloride	Carvedilol
Amlodipine Besylate	Bethanechol Chloride	Caspofungin Acetate
Amlodipine Besylate/Benazepril Hydrochloride	Bevacizumab	Celecoxib
Amoxicillin/Clarithromycin/ Lansoprazole	Bimatoprost	Cetirizine Hydrochloride
Amphetamine Aspartate/ Amphetamine Sulfate/ Dextroamphetamine Saccharate/ Dextroamphetamine Sulfate	Bisacodyl/Polyethylene Glycol/ Potassium Chloride/ Sodium Bicarbonate/ Sodium Chloride	Cetuximab
Amprenavir	Bisoprolol Fumarate	Cevimeline Hydrochloride
Anagrelide Hydrochloride	Bisoprolol Fumarate/ Hydrochlorothiazide	Chloramphenicol
Anthralin	Bitolterol Mesylate	Chloroprocaine Hydrochloride
Antihemophilic Factor (Human)	Black Widow Spider Antivenin (Equine)	Chlorothiazide
Antihemophilic Factor (Recombinant)	Botulinum Toxin Type A	Chlorothiazide Sodium
Anti-Inhibitor Coagulant Complex	Botulinum Toxin Type B	Chlorpheniramine Maleate/ Methscopolamine Nitrate/ Phenylephrine Hydrochloride
Anti-Thymocyte Globulin	Brinzolamide	Chlorpheniramine Maleate/ Pseudoephedrine Hydrochloride
Apomorphine Hydrochloride	Brompheniramine Maleate/ Dextromethorphan	Chlorpheniramine Polistirex/ Hydrocodone Polistirex
Aripiprazole	Hydrobromide/Phenylephrine Hydrochloride	Chlorpheniramine Tannate/ Phenylephrine Tannate
Arnica Montana/Herbals, Multiple/ Sulfur	Budesonide	Chlorpropamide
Asparaginase	Bupivacaine Hydrochloride	Chlorhalidone/Clonidine Hydrochloride
Atomoxetine Hydrochloride	Bupivacaine Hydrochloride/ Epinephrine Bitartrate	Choline Magnesium Trisalicylate
Atovaquone	Buprenorphine Hydrochloride	Cidofovir
Atovaquone/Proguanil Hydrochloride	Buprenorphine Hydrochloride/ Naloxone Hydrochloride	Cilostazol
Atropine Sulfate/Benzoic Acid/Hyoscyamine Sulfate/ Mathenamine/Methylene Blue/ Phenyl Salicylate	Butabarbital/Hyoscyamine Hydrobromide/Phenazopyridine Hydrochloride	Cinacalcet Hydrochloride
Atropine Sulfate/Hyoscyamine Sulfate/Scopolamine Hydrobromide	Butalbital/Acetaminophen	Ciprofloxacin Hydrochloride
Azelastine Hydrochloride	Butenafine Hydrochloride	Ciprofloxacin Hydrochloride/ Hydrocortisone
Bacitracin Zinc/Neomycin Sulfate/ Polymyxin B Sulfate	Butoconazole Nitrate	Ciprofloxacin/Dexamethasone
Baclofen	Butorphanol Tartrate	Citalopram Hydrobromide
Bcg. Live (Intravesical)	Caffeine Citrate	Clarithromycin
Becaplermin	Calcipotriene	Clobetasol Propionate
Beclomethasone Dipropionate	Calcitonin-Salmon	Clonidine
Beclomethasone Dipropionate Monohydrate	Calcitriol	Clonidine Hydrochloride
Benazepril Hydrochloride*	Calcium Acetate	Codeine Phosphate/Acetaminophen
Benazepril Hydrochloride/ Hydrochlorothiazide*	Candesartan Cilexetil*	Colistimethate Sodium
Bendroflumethiazide	Candesartan Cilexetil/ Hydrochlorothiazide*	Colistin Sulfate/Hydrocortisone Acetate/Neomycin Sulfate/ Thonzonium Bromide
Benzocaine	Capreomycin Sulfate	Corticotropin Ovine Triflutate
Benzonate	Captropil*	Cycloserine
	Carbetapentane Tannate/ Chlorpheniramine Tannate	

\*Category C or D depending on the trimester the drug is given.

Cyclosporine	Eletriptan Hydrobromide	Fluticasone Propionate/Salmeterol Xinafoate
Cytomegalovirus Immune Globulin	Enalapril Maleate*	Fomivirsen Sodium
Dacarbazine	Enalapril Maleate/Felodipine*	Formoterol Fumarate
Daclizumab	Enalapril Maleate/Hydrochlorothiazide*	Fosamprenavir Calcium
Dantrolene Sodium	Entacapone	Foscarnet Sodium*
Dapsone	Entecavir	Fosinopril Sodium*
Darbepoetin Alfa	Epinastine Hydrochloride	Fosinopril Sodium/ Hydrochlorothiazide*
Darifenacin	Epinephrine	Frovatriptan Succinate
Deferoxamine Mesylate	Epoetin Alfa	Furosamide
Delavirdine Mesylate	Eprosartan Mesylate	Gabapentin
Denileukin Diftitox	Erythromycin Ethylsuccinate/ Sulfisoxazole Acetyl	Gallium Nitrate
Desloratadine Desloratadine/ Pseudoephedrine Sulfate	Escitalopram Oxalate	Ganciclovir
Desoximetasone	Esmolol Hydrochloride	Ganciclovir Sodium
Dexamethasone	Eszopiclone	Gatifloxacin
Dexamethasone Sodium Phosphate	Ethionamide	Gemfibrozil
Dexmethylphenidate Hydrochloride	Ethotoin	Gemifloxacin Mesylate
Dexrazoxane	Etidronate Disodium	Gentamicin Sulfate
Dextroamphetamine Sulfate	Exenatide	Gentamicin Sulfate/Prednisolone Acetate
Diazoxide	Ezetimibe	Glimepiride
Dichlorophenamide	Factor Ix Complex	Glipzide
Diclofenac Potassium	Felodipine	Glipizide/Metformin Hydrochloride
Diclofenac Sodium	Fenofibrate	Globulin, Immune (Human)
Diflorasone Diacetate	Fentanyl	Globulin, Immune (Human)/Rho (D) Immune Globulin (Human)
Diflunisal	Fentanyl Citrate	Glyburid
Digoxin	Ferrous Fumarate/Folic Acid/ Intrinsic Factor Concentrate/ Liver Preparations/Vitamin B12/ Vitamin C/Vitamins with Iron	Gramicidin/Neomycin Sulfate/ Polymyxin B Sulfate
Digoxin Immune Fab (Ovine)	Fexofenadine Hydrochloride	Guaifenesin/Hydrocodone Bitartrate
Diltiazem Hydrochloride	Fexofenadine Hydrochloride/ Pseudoephedrine Hydrochloride	Haemophilus B Conjugate Vaccine
Dimethyl Sulfoxide	Filgrastim	Haemophilus B Conjugate Vaccine/ Hepatitis B Vaccine, Recombinant
Dinoprostone	Flecainide Acetate	Halobetasol Propionate
Diphtheria & Tetanus Toxoids and Acellular Pertussis Vaccine Adsorbed	Fluconazole	Haloperidol Decanoate
Diphtheria & Tetanus Toxoids and Acellular Pertussis Vaccine Adsorbed/Hepatitis B Vaccine, Recombinant/Poliovirus Vaccine Inactivated	Flucytosine	Hemin
Dirithromycin	Fludrocortisone Acetate	Heparin Sodium
Dofetilide	Flumazenil	Hepatitis A Vaccine, Inactivated
Donepezil Hydrochloride	Flunisolide	Hepatitis A Vaccine, Inactivated/ Hepatitis B Vaccine, Recombinant
Dorzolamide Hydrochloride	Fluocinolone Acetonide	Hepatitis B Immune Globulin (Human)
Dorzolamide Hydrochloride/Timolol Maleate	Fluocinolone Acetonide/ Hydroquinone/Tretinoin	Hepatitis B Vaccine, Recombinant
Doxazosin Mesylate	Fluocinonide	Homatropine Methylbromide/ Hydrocodone Bitartrate
Dronabinol	Fluoromethalone	Homeopathic Formulations
Drotrecogin Alfa (Activated)	Fluorometholone/Sulfacetamide Sodium	Hydralazine Hydrochloride/ Isosorbide Dinitrate
Duloxetine Hydrochloride	Fluoxetine Hydrochloride	Hydrochlorothiazide
Echothiophate Iodide	Fluoxetine Hydrochloride/Olanzapine	Hydrocodone Bitartrate
Econazole Nitrate	Flurandrenolide	Hydrocodone Bitartrate/ Acetaminophen
Efalizumab	Flurbiprofen Sodium	
Elfornithine Hydrochloride	Fluticasone Propionate	
	Fluticasone Propionate Hfa	

(Continued on next page)

\*Category C or D depending on the trimester the drug is given.

Hydrocodone Bitartrate/Ibuprofen	Lamivudin/Zidovudine	Metipranolol
Hydrocortisone	Lamotrigine	Metoprolol Succinate
Hydrocortisone Acetate	Lanthanum Carbonate	Metoprolol Tartrate
Hydrocortisone Acetate/ Neomycin Sulfate/Polymyxin B Sulfate	Latanoprost	Metoprolol Tartrate/ Hydrochlorothiazide
Hydrocortisone Acetate/Pramoxine Hydrochloride	Levalbuterol Hydrochloride	Metyrosine
Hydrocortisone Butyrate	Levalbuterol Tartrate	Mexiletine Hydrochloride
Hydrocortisone Probutate	Levamisole Hydrochloride	Micafungin Sodium
Hydrocortisone/Neomycin Sulfate/ Polymyxin B Sulfate	Levetiracetam	Midodrine Hydrochloride
Hydromorphone Hydrochloride	Levobunolol Hydrochloride	Mivacurium Chloride
Hydroquinone	Levofloxacin	Modafinil
Hyoscyamine Sulfate	Linezolid	Moexipril Hydrochloride*
Ibandronate Sodium	Lisinopril*	Moexipril Hydrochloride/ Hydrochlorothiazide*
Ibutilide Fumarate	Lisinopril/Hydrochlorothiazide*	Mometasone Furoate
Iloprost	Lopinavir Ritonavir	Mometasone Furoate Monohydrate
Imiglucerase	Losartan Potassium*	Morphine Sulfate
Imipenem/Cilastatin	Losartan Potassium/ Hydrochlorothiazide*	Morphine Sulfate, Liposomal
Imiquimod	Loteprednol Etabonate	Moxifloxacin Hydrochloride
Immune Globulin Intravenous (Human)	Mafenide Acetate	Mumps Virus Vaccine, Live
Indinavir Sulfate	Magnesium Salicylate Tetrahydrate	Muromonab-Cd3
Indocyanine Green	Measles Virus Vaccine, Live	Mycophenolate Mofetil
Influenza Virus Vaccine	Measles, Mumps & Rubella Virus Vaccine, Live	Mycophenolate Mofetil Hydrochloride
Insulin Aspart	Mebendazole	Mycophenolic Acid
Insulin Aspart Protamine, Human/ Insulin Aspart, Human	Mecamylamine Hydrochloride	Nabumetone
Insulin Glargine	Mecasermin [Rdna Origin]	Nadolol
Insulin Glulisine	Medrysone	Nadolol/Bendroflumethiazide
Interferon Alfa-2A, Recombinant	Mefenamic Acid	Naloxone Hydrochloride/Pentazocine Hydrochloride
Interferon Alfa-2B, Recombinant	Mefloquine Hydrochloride	Naltrexone Hydrochloride
Interferon Alfacon-1	Meloxicam	Naphazoline Hydrochloride
Interferon Alfa-N3 (Human Leukocyte Derived)	Meningoccal Polysaccharide Diphtheria Toxoid Conjugate Vaccine	Naproxen
Interferon Beta-1A	Meningoccal Polysaccharide Vaccine	Naproxen Sodium
Interferon Beta-1B	Meperidine Hydrochloride	Naratriptan Hydrochloride
Interferon Gamma-1B	Mepivacaine Hydrochloride	Natamycin
Iodoquinol/Hydrocortisone	Metaproterenol Sulfate	Nateglinide
Irbesartan*	Mitraminol Bitartate	Nefazodone Hydrochloride
Irbesarran/Hydrochlorothiazide*	Metformin Hydrochloride/ Pioglitazone Hydrochloride	Neomycin Sulfate/Dexamethasone Sodium Phosphate
Iron Dextran	Metformin Hydrochloride/ Rosiglitazone Maleate	Neomycin Sulfate/Polymyxin B Sulfate/Prednisolone Acetate
Isoniazid/Pyrazinamide/Rifampin	Methamphetamine Hydrochloride	Nesiritide
Isosorbide Mononitrate	Methazolamide	Nevirapine
Isradipine	Methenamine Mandelate/Sodium Acid Phosphate	Niacin
Itraconazole	Methocarbamol	Nicardipine Hydrochloride
Ivermectin	Methoxsafen	Nifedipine
Ketoconazole	Methscopolamine Nitrate/ Pseudoephedrine Hydrochloride	Nilutamide
Ketorolac Tromethamine	Methyldopa/Chlorothiazide	Nimodipine
Ketotifen Fumarate	Methyldopa/Hydrochlorothiazide	Nisoldipine
Labetalol Hydrochloride	Methylphenidate Hydrochloride	Nitroglycerin
Lamivudine		Norfloxacin
		Ofloxacin
		Olanzapine

\*Category C or D depending on the trimester the drug is given.

Olmesartan Medoxomil/ Hydrochlorothiazide	Polyethylene Glycol/Potassium Chloride/Sodium Bicarbonate/ Sodium Chloride/Sodium Sulfate	Rocuronium Bromide
Olopatadine Hydrochloride	Polymyxin B Sulfate/Trimethoprim Sulfate	Rofecoxib
Olsalazine Sodium	Polythiazide/Prazosin Hydrochloride	Ropinireole Hydrochloride
Omega-3-Acid Ethyl Esters	Porfimer Sodium	Rosiglitazone Maleate
Omeprazole	Potassium Acid Phosphate	Rubella Virus Vaccine, Live
Oprelvekin	Potassium Chloride	Salmeterol Xinafoate
Orphenadrine Citrate	Potassium Citrate	Sargamostim
Oseltamivir Phosphate	Potassium Phosphate/Sodium Phosphate	Scopolamine
Oxcarbazepine	Pralidoxime Chloride	Selegiline Hydrochloride
Oxycodone Hydrochloride/ Acetaminophen	Pramipexole Dihydrochloride	Sertaconazole Nitrate
Oxycodone Hydrochloride/Ibuprofen	Pramlintide Acetate	Sertraline Hydrochloride
Oxymorphone Hydrochloride	Pramoxine Hydrochloride/Hydrocortisone Acetate	Sevelamer Hydrochloride
Palifermin	Prazosin Hydrochloride	Sibutramine Hydrochloride Monohydrate
Palivizumab	Prednisolone Acetate	Sirolimus
Pancrelipase	Prednisolone Acetate/Sulfacernamide Sodium	Sodium Benzoate/Sodium Phenylacetate
Paricalcitol	Prednisolone Sodium Phosphate	Sodium Phenylbutyrate
Paroxetine Hydrochloride	Pregabalin	Sodium Sulfacetamide/Sulfur
Paroxetine Mesylate	Proclainamide Hydrochloride	Solifenacin Succinate
Peg-3350/Potassium Chloride/ Sodium Bicarbonate/Sodium Chloride	Promethazine Hydrochloride	Somatropin
Pegademase Bovine	Propafenone Hydrochloride	Somatropin (rDNA Origin)
Pegaspargase	Proparacaine Hydrochloride	Stavudine
Pegfilgrastim	Propranolol Hydrochloride	Streptokinase
Peginterferon Alfa-2A	Pseudoephedrine Hydrochloride	Succimer
Peginterferon Alfa-2B	Pyrimethamine	Sulfacetamide Sodium
Pemirolast Potassium	Quetiapine Fumarate	Sulfamethoxazole/Trimethoprim
Pentazocine Hydrochloride/ Acetaminophen	Quinapril Hydrochloride*	Sulfanilamide
Pentoxifylline	Quinidine Sulfate	Sumatriptan
Perindopril Erbumine*	Rabies Vaccine	Sumatriptan Succinate
Phenoxybenzamine Hydrochloride	Ramelteon	Tacrine Hydrochloride
Phentermine Hydrochloride	Ramipril*	Tacrolimus
Pilocarpine Hydrochloride	Rasburicase	Telithromycin
Pimercrolimus	Remifentanil Hydrochloride	Telmisartan*
Pimozide	Repaglinide	Telmisartan/Hydrochlorothiazide*
Pioglitazone Hydrochloride	Reteplase	Tenecteplase
Pirbuterol Acetate	Rho (D) Immune Globulin (Human)	Terazosin Hydrochloride
Piroxicam	Rifampin	Teriparatide
Plasma Fractions, Human/Rabies Immune Globulin (Human)	Rifapentine	Tetanus & Diphtheria Toxoids Adsorbed
Plasma Protein Fraction (Human)	Rifamixin	Tetanus Immune Globulin (Human)
Pneumococcal Vaccine, Diphtheria Conjugate	Riluzole	Theophylline
Pneumococcal Vaccine, Polyvalent	Rimantadine Hydrochloride	Theophylline Anhydrous
Podofilox	Risedronate Sodium	Thiabendazole
Polyethylene Glycol	Risedronate Sodium/Calcium Carbonate	Thrombin
Polyethylene Glycol/Potassium Chloride/Sodium Bicarbonate/ Sodium Chloride	Risperidone	Thyrotropin Alfa
	Rituximab	Tiagabine Hydrochloride
	Rizatriptan Benzoate	Tiludronate Disodium
		Timolol Hemihydrate
		Timolol Maleate
		Timolol Maleate/ Hydrochlorothiazide

(Continued on next page)

\*Category C or D depending on the trimester the drug is given.

Tinidazole  
 Tiotropium Bromide  
 Tipranavir  
 Tizanidine Hydrochloride  
 Tobramycin/Dexamethasone  
 Tobramycin/Loteprednol Etabonate  
 Tolcapone  
 Tolterodine Tartrate  
 Topiramate  
 Tramadol Hydrochloride  
 Tramadol Hydrochloride/  
 Acetaminophen  
 Trandolapril\*  
 Trandolapril/Verapamil  
 Hydrochloride\*  
 Travoprost

Sarafem	Triphasil	Zydone
Seconal	Trivora	Zyloprim
Sectral	Trizivir	Zyprexa
Semprex-D	Trovan	Zyrtec

## LOW POTASSIUM DIET

### Lexi-Drugs Online

Potassium is a mineral found in most all foods except sugar and lard. It plays a role in maintaining normal muscle activity and helps to keep body fluids in balance. Too much potassium in the blood can lead to changes in heartbeat and can lead to muscle weakness. The kidneys normally help to keep blood potassium controlled, but in kidney disease or when certain drugs are taken, dietary potassium must be limited to maintain a normal level of potassium in the blood. The following guideline includes 2–3 g of potassium per day.

**Milk Group:** Limit to one cup serving of milk or milk product (yogurt, cottage cheese, ice cream, pudding).

**Fruit Group:** Limit to two servings daily from the low potassium choices. Watch serving sizes. Avoid the high potassium choices.

#### Low Potassium

Apple, 1 small  
 Apple juice, applesauce ½ cup  
 Apricot, 1 medium or ½ cup canned in syrup  
 Blueberries, ½ cup  
 Cherries, canned in syrup ⅓ cup  
 Cranberries, cranberry juice ½ cup  
 Fruit cocktail, canned in syrup ½ cup  
 Grapes, 10 fresh  
 Lemon, lime 1 fresh  
 Mandarin orange, canned in syrup ½ cup

Nectar: apricot, pear, peach ½ cup  
 Peach, 1 small or ½ cup canned with syrup  
 Pear, 1 small or ½ cup canned with syrup  
 Pineapple, ½ cup raw or canned with syrup  
 Plums, 1 small or ½ cup canned with syrup  
 Tangerine, 1 small  
 Watermelon, ½ cup

#### High Potassium

Avocado  
 Banana  
 Cantaloupe  
 Cherries, fresh  
 Dried fruits  
 Grapefruit, fresh and juice  
 Honeydew melon  
 Kiwi  
 Mango  
 Nectarine  
 Orange, fresh and juice  
 Papaya  
 Prunes, prune juice  
 Raisins

Avoid use of the following salt substitutes due to their high potassium contents: Adolph's, Lawry's Season Salt Substitute, No Salt, Morton Season Salt Free, Nu Salt, Papa Dash, and Morton Lite Salt.

# Budgeting for Drug Information Resources

## Basic Library

References	Cost <sup>a</sup>
<i>American Hospital Formulary Service (AHFS) Drug Information</i>	\$ 239.00
<i>Drug Facts and Comparisons</i>	\$ 226.95
<i>Handbook on Injectable Drugs</i>	\$ 234.00
<i>Handbook of Non-Prescription Drugs: An Interactive Approach to Self-Care</i>	\$ 149.95
<i>Martindale: The Complete Drug Reference</i>	\$ 550.00
<i>Nonprescription Product Therapeutics</i>	\$ 94.95
<i>Physicians' Desk Reference</i>	\$ 94.95
<i>Remington's Pharmaceutical Sciences</i>	\$ 137.00
<i>USP DI (three-volume set)</i>	\$ 412.00

## Additional Resources

References	Cost <sup>a</sup>
<b>Drug–drug interaction</b>	
<i>Drug Interactions Analysis and Management</i>	\$ 210.00
<i>Drug Interaction Facts</i>	\$ 235.00
<i>Evaluations of Drug Interactions</i>	\$ 240.00
<b>Herbal</b>	
<i>PDR for Herbal Medicines</i>	\$ 59.95
<i>The Review of Natural Products</i>	\$ 169.00
<i>Natural Medicine Comprehensive Database</i>	\$ 92.00
<i>Natural Standard Herb and Supplement Reference</i>	\$ 133.00
<b>Internal medicine</b>	
<i>Cecil Medicine</i>	\$ 219.00
<i>Harrison's Principles of Internal Medicine</i>	\$ 137.75
<b>Pediatrics</b>	
<i>Pediatric Dosage Handbook</i>	\$ 49.95
<i>The Harriet Lane Handbook</i>	\$ 54.95
<b>Pharmacokinetics</b>	
<i>Applied Biopharmaceutics and Pharmacokinetics</i>	\$ 62.95
<i>Clinical Pharmacokinetics</i>	\$ 46.00
<i>Concepts in Clinical Pharmacokinetics</i>	\$ 66.00
<i>Applied Pharmacokinetics and Pharmacodynamics: Principles of Therapeutic Drug Monitoring</i>	\$ 79.95
<b>Pharmacology</b>	
<i>Goodman and Gilman's The Pharmacological Basis of Therapeutics</i>	\$ 140.00
<b>Pregnancy/breast-feeding</b>	
<i>Drugs in Pregnancy and Lactation</i>	\$ 99.00

(Continued on next page)

(Continued)

References	Cost <sup>a</sup>
<b>Therapeutics</b>	
<i>Applied Therapeutics: The Clinical Use of Drugs</i>	\$ 213.00
<i>Pharmacotherapy: A Pathophysiologic Approach</i>	\$ 206.00
<i>Textbook of Therapeutics: Drug and Disease Management</i>	\$ 213.00
<b>CD ROM computer systems/programs</b>	
<i>Clinical Pharmacology</i>	\$ 5,800.00
<i>Lexi-Comp Online</i>	\$ 3,000.00
<i>DataKinetics</i>	\$ 1,225.00
<i>Facts and Comparisons 4.0 (online)</i>	\$ 2,000.00
<i>Iowa Drug Information System</i>	\$ 9,000+
<i>IPA</i>	\$ 3,000+
<i>Medline</i>	\$ 20,000+
<i>MedTeach Patient Education Program</i>	\$ 611.00
<i>UPTODATE (stand alone)</i>	\$ 1,611.93
<b>Micromedex</b>	
<i>Diseasedex</i>	Must contact representative for price
<i>Drugdex</i>	Must contact representative for price
<i>Poisindex</i>	Must contact representative for price
<b>Other Micromedex databases</b>	
<i>CareNotes</i>	Must contact representative for price
<i>Drug-Reax</i>	Must contact representative for price
<i>Kinetidex</i>	Must contact representative for price

<sup>a</sup>Costs are approximate and are based on 2007 figures. Costs vary depending upon selection of format site versus individual license fees, concurrent users, number of beds in facility, or number of students enrolled. Institutional subscriptions are more expensive than individual subscriptions. It is important to have the appropriate site license.

# Index

Page numbers in italic type indicate items found in the supplemental online chapters and page numbers followed by an *f* or *t* denotes figures and tables respectively.

- A1c testing, 932–933, 933*t*, 943  
Abacavir, 158, 682*t*, 725, 726*t*, 728–729  
Abarelix, 1009*t*  
Abatacept, 870*t*, 871, 1021*t*  
Abbreviated New Drug Application (ANDA), 122–123, 1076  
Abbreviations, errors associated with, 1197–1198  
Abciximab, 135, 136*t*  
    for STEMI, 582*t*  
    for unstable angina and NSTEMI, 580  
Abdominal supports, 368  
ABO blood group system, 1056  
Abortifacients, 228  
Abrasive denture cleansers, 382  
Abrasives, in toothpaste, 377  
Abscess, in Crohn disease, 927  
Absence seizures, 744*t*, 746, 753*t*  
Absolute bioavailability (*F*), 115, 126  
Absolute refractory period, 592  
Absolute risk (AR), 309  
Absolute temperature, 19  
Absorption  
    administration route and, 71–72  
    bioavailability and, 75  
    of dietary fat, 424, 426  
    drug interactions involving, 272–274  
    of exogenous molecules, 71  
    first-order, 105, 105*f*  
    in geriatric patients, 520  
    lag time of, 106  
    local drug activity *v.* systemic drug absorption, 72  
    mean absorption time, 115  
    metabolism and, 153  
    pediatric, 511–512  
    placental drug transfer and, 530  
    solubility and, 73  
    time for maximum, 105  
    transport across cell membrane, 69–71, 69*f*  
    zero-order, 106, 106*f*  
Absorption bases, in ointments, 42  
Abstinence, contraception methods using, 474  
Abstracting services, 290–291, 291*t*  
Acacia, 37, 39–41, 87  
Acarbose, 265*f*, 266, 938*t*, 941, 944  
Accelerated testing, shelf-life determination with, 34  
Accumulation rate, 108  
Accuracy, 543  
ACDs. *See* Automated compounding devices  
Acebutolol  
    for angina pectoris, 574*t*  
    for arrhythmias, 597*t*, 603–604  
    for hypertension, 619*t*, 624  
    nervous system actions of, 171, 171*t*, 173  
ACE inhibitors. *See* Angiotensin-converting enzyme inhibitors  
Acetaminophen  
    for acute necrotizing ulcerative gingivitis, 380  
    with amphotericin B administration, 702  
    analgesic and antipyretic effects of, 232, 232*f*, 438–439  
    for common cold, 448–449  
    for dental caries, 376  
    dosage, 1021*t*  
    double-peak phenomenon, 72  
    drug interactions of, 277*t*, 281*t*, 282*t*, 439, 482, 696, 756, 1024  
    for dysmenorrhea, 469  
    for gingivitis, 379  
    hepatotoxicity of, 232, 438–439, 992–993  
    metabolism of, 143–144, 144*f*, 145*f*, 152–153  
    with nitrate administration, 572  
    for osteoarthritis, 865  
    in pediatric patients, 513  
    for PMS/PMDD, 528  
    in sleep aids, 427–428  
    for temporomandibular joint syndrome, 380  
    toxic ingestion of, 320–321  
Acetate, in parenteral preparations, 350  
Acetazolamide  
    drug interactions of, 695, 759  
    for hypertension, 204, 204*f*  
    hypobicarbonatemia caused by, 554  
    urinalysis and, 550  
Acetic acid derivatives, 229, 230*f*  
Acetoacetic acid, 550  
Acetohexamide, 263, 264*t*  
Acetone, in urine, 550  
Acetylation, 149*t*, 151–152  
Acetylcholine (ACh), 171, 172*f*, 236  
Acetylcholine receptors, 1119  
Acetylcholinesterase (AChE), 171  
Acetylcholinesterase inhibitors, 173–174, 174*f*, 177  
Acetylcysteine, 572, 850

 renal cortical imaging agents, 1168  
 tubular secretion agents, 1167  
 skeletal imaging, 1164  
 sodium pertechnetate <sup>99m</sup>Tc generator,  
 1161–1162  
 therapeutic agents, 1174–1176  
 samarium-153 lexidronam, 1175  
 sodium iodide, 1174  
 strontium-89 chloride, 1174  
 yttrium-90 ibritumomab tiuxetan,  
 1175–1176  
 thyroid imaging, 1168–1169  
 tumors, 1173–1174
- RAI. *See* Radioactive iodine
- Raloxifene, 248–249, 249*f*, 1009*t*  
 osteoporosis treatment with, 261, 538,  
 539*t*  
 thyroid function test effect of, 960*t*  
 TSH levels and, 964*t*
- Raltegravir, 683*t*, 725, 726*t*, 735
- Ramelteon  
 drug interactions of, 277*t*, 282  
 for insomnia, 822–824, 823*t*  
 nervous system effects of, 181
- Ramipril  
 for heart failure, 648, 649*t*  
 for hypertension, 199*f*, 200, 619*t*,  
 628–629, 634
- Random allocation, 297
- Random controlled trial (RCT), 310
- Randomized trials, 311–312
- Range, 303
- Ranibizumab, 136*t*
- Ranitidine, 239  
 drug interactions of, 457  
 for heartburn and dyspepsia, 466  
 metabolism of, 146*t*  
 for PUD, 895–897, 895*t*
- Ranolazine, 207
- Raoult's law, 24
- Rasagiline, 782*t*, 785
- Rasburicase, 138, 234, 287*t*, 1015
- Rash, drug-induced photosensitivity  
 causing, 410
- Rate constants  
 elimination, 104, 110  
 first-order, 103  
 hybrid first order, 109  
 zero-order, 103
- Rate-limiting step, in bioavailability, 75
- Rate of decomposition, 34
- Rate of excretion in urine, 125
- Rate of infusion, for IV infusion, 106
- Rate of reaction, 30–32, 31*f*, 102–103  
 factors affecting, 32–33, 33*f*
- Rate of shear, 21
- Rate ratio. *See* Relative risk

 width
- Reactant concentration  
 in first-order reactions, 31, 31*f*  
 in zero-order reactions, 30, 31*f*
- Reactions  
 orders of, 30–32, 31*f*, 102–103  
 rates of, 30–32, 31*f*, 102–103  
 factors affecting, 32–33, 33*f*
- Reassortment, in viruses, 1093
- Rebound hyperglycemia, 936
- Receptor ligands, 1150
- Receptors, 1135–1137  
 cell surface, signal transduction and,  
 1135–1136, 1135*f*, 1136*f*  
 drug–receptor interactions, 1137–1140  
 binding, 1137–1138, 1138*f*  
 drugs as agonists, 1138–1139, 1139*f*  
 drugs as antagonists, 1139–1140,  
 1139*f*  
 enzymes as drug receptors, 1140  
 modulation of receptor sensitivity,  
 1140  
 intracellular, 1137, 1137*f*  
 microorganism proteins as drug  
 targets, 1137
- Reciprocal walker, 363
- Recombinant DNA (rDNA), 134  
 insulin prepared with, 261
- Recombinant factor VII, 323
- Recombinant factor VIIa, 323
- Recombinant growth hormone,  
 1049–1050
- Recombinant plasminogen activator  
 (r-PA), 583–584
- Reconstituted medications, aseptic  
 technique for, 342
- Reconstitution  
 of dry powder from a vial, 97–98, 346  
 of powders, aseptic technique for, 342
- Recovery, 1094
- Rectal administration, 72, 153, 512
- Rectal suppositories, 44–45, 96
- Rectal temperature, 370
- Recurrent aphthous stomatitis. *See* Canker  
 sores
- Recurrent aphthous ulcers. *See* Canker  
 sores
- Red blood cell distribution width
